Electromagnetic interference (EMI) from radiofrequency sources may cause a variety of medical devices to malfunction and compromise patient safety. An overview of the following EMI issues is presented: Interference with medical devices, including implantable cardiac devices, from wireless telecommunication systems, wireless local area network systems, electronic article surveillance systems, and metal detectors and assessment of the susceptibility of medical devices to EMI from these sources. This chapter includes recommendations on solutions to minimize risk and a review of international standards on electromagnetic compatibility (EMC) requirements.

Electromagnetic Interference

Electromagnetic interference (EMI) is a phenomenon that may occur when an electronic device is exposed to an electromagnetic (EM) field. Any device that has electronic circuitry can be susceptible to EMI. With the ever-increasing use of the electromagnetic spectrum and the more complex and sophisticated electronic devices, issues of EMI are attracting attention. When addressing EMI issues, consider a source, a path, and a receptor. The electromagnetic energy from the source propagates through the path and interferes with the operation of the receptor. All three must exist to have an EMI problem. The path can be conducted, radiated, inductive, or coupled with a capacitor or with electrostatic discharges, or a combination of any of the above. Therefore, to understand the effects of EMI, consider two factors: Emissions and immunity (also known as susceptibility). Emissions are a measure of electromagnetic energy from a radiofrequency source. Immunity concerns the degree of interference from an external electromagnetic energy source on the operation of the electronic device. The device will be immune below a certain level of EMI and become susceptible above that level. The three most common EMI problems are radio frequency interference, electrostatic discharge, and power disturbances. This chapter will focus on radiated interference from various radiofrequency sources.

Interference with Medical Devices

The operation of components of modern medical electronic devices such as sensitive analog amplifiers and sophisticated microprocessors can be disrupted by EMI when electromagnetic field strengths in the surrounding environment are greater than the immunity of the medical device. Electromagnetic interference has been responsible for many life-support and critical care medical device malfunctions, which raises concerns about the safety of patients who depend on these devices. Numerous incidents involving EMI with medical electrical equipment have been reported to regulatory agencies in Canada, the United

States, the United Kingdom, and Australia, and published in scientific journals (Silverberg, 1993; Hayes et al., 1997; Carillo et al., 1996). Sources of interference include wireless telecommunication systems, electronic security systems, electrosurgical devices, electrostatic discharge, and electrical disturbances from main power supply systems. However, the incidence of unreported EMI malfunctions is unknown. Between 1984 and 2000, Health Canada's Medical Devices Bureau (MDB) received 36 reports of medical device malfunction attributed to EMI (MDB, 2000; Tan and Segal, 1995). These included four reports of medical device malfunctions caused by wireless cellular phones, two cases of EMI interference from electronic article surveillance (EAS) systems on implantable cardiac pacemakers, and possibly one case of decreasing battery voltage of a pacemaker and activating the premature failure error message. The MDB also investigated reports of interference from other radiofrequency sources. These included interference of an electrosurgical device with the electrocardiogram signals displayed on the monitor of an automated external defibrillator; complete inhibition of the pacing signal of a pacemaker by a pulsating magnetic field from a video display terminal; failure of the R-wave detection circuitry of a cardiac defibrillator in the presence of a simulated muscle artifact signal from an electrocardiogram simulator; and interference of the line-isolation system in an intensive care unit with the performance of a defibrillator. These reports highlight the need for guidelines on the management of EMI within hospitals, especially in critical care areas.

The United States Food and Drug Administration Center for Devices and Radiological Health (FDA, CDRH) has also evaluated the potential EMI risks to medical devices based on the CDRH MedWatch incident report system. Silberberg published a report that cites 101 incidents the FDA received from 1979 to 1993 (Silberberg, 1992; Silberberg, 1993). Witters et al. reported in 2001 that 576 out of 150,000 incident reports received between 1984 and 1995 were found likely to be related to EMI. About 79%, or 456, of these reports involved implantable cardiac pacemakers and defibrillators, and indicated that intervention was needed to protect patients. They also reported that, in the last 10 years, the FDA has received more than 80 EMI-related reports related to security systems, such as EAS systems and metal detectors.

Hospital staff, including biomedical and clinical engineers, clinicians, nurses, and administrators, as well as the general public, have expressed concerns about EMI based on incident reports and other publications. Frequently asked questions include: What is the safe distance between a cell phone and a medical device or a pacemaker? Should hospital ban the use of cell phones? Will the cell phone affect cardiac pacemakers? Will the EAS system affect the pacemaker? Can hospital use the use new wireless LAN system? Will any wireless communication systems or security systems cause inappropriate inhibition or triggering of a pacemaker pacing output, or activate asynchronous pacing on a cardiac pacemaker? Will such systems reprogram the pacemaker to a backup mode, permanently damage the pacemaker, or inappropriately trigger an implantable cardioverter defibrillator (ICD)?

Electronic circuits of cardiac pacemakers resist EMI only up to a low level of radiation. At higher levels, pacemakers react by switching to a fixed-rate mode. Strong, amplitude-

modulated, low- or high-frequency EM fields can cause asynchronous pacing as well as an inhibition of the pacemaker's stimulation function. Since the introduction of wireless hand-held cell phones, the user carries not only a receiver, but also a transmitter close to the body. The transmitter emits relatively strong EM fields into the body. The emitted EM waves, with their analog, digital, or both kinds of modulation, penetrate the body, where they can influence existing electronic implants, such as pacemakers. Several research groups have investigated the interference on implantable cardiac pacemakers in the proximity of cell phones (Tan and Hinberg, 1998; Hayes and Wang, 1997; Carillo et al., 1996; Barbaro et al., 1995; Eicher et al., 1994; Imich et al., 1996; Schlegal et al., 1995; Hayes et al., 1996). In addition, researchers have reported effects of other commercial radiofrequency instruments, such as security systems, on implantable medical devices (Tan and Hinberg, 1998; Tan and Hinberg, 1999; Dodinot et al., 1993; Lucas et al., 1994; McIvor, 1995; Mathew et al., 1997; Copperman et al., 1988).

To identify emerging EMI issues, concerns, and risk management strategies, the authors investigated the susceptibility of critical care medical devices to various radiofrequency sources and assessed the risks. The sources were the following: Wireless telecommunication devices, such as analog and digital cellular phones, two-way radios, personal communication service (PCS) systems, companion technology systems, family radio services (FRS) systems wireless local area network (LAN) systems, medical telemetry systems, electronic security systems, such as EAS systems, walk-through metal detectors (WTMDs) and hand-held metal detectors (HHMDs). Medical devices used in these studies included 29 therapeutic devices, 13 monitoring devices, 10 diagnostic medical devices, 22 implantable cardiac pacemakers, and 2 implantable defibrillators. The degree to which medical electrical devices are affected by radiofrequency sources depends on the device's susceptibility to the EMI, the power and the operating frequency of the radiated sources, and the distance of the medical electrical equipment from the radiated sources.

Electric and Magnetic Field Strengths from Various Radiofrequency Sources

Before any EMI testing was done on medical devices, the researchers measured electric and magnetic field strength from various radiofrequency radiated sources as a function of distances or operating frequencies. An adjustable dipole antenna, EMCO model 3121C and an Amplifier Research log periodic antenna model AT1000, were used to measure the electric field intensity radiating from the source. The output of the antenna was connected to a spectrum analyzer (Hewlett Packard models E8541 and model E4407B). EMCO passive loop antennas, models 7604 and 6509, were used to measure magnetic field intensity generated from the source. In either case, electric and magnetic field strengths were calculated from the values obtained by the spectrum analyzer, to which both the frequency-dependent antenna factor and cable loss were added.

Wireless Telecommunication Devices

Figure 62-1 shows the electric field strengths as measured from four two-way radios and one cell phone as a function of distances. Four models of cell phones were tested with similar results. At a distance of 1 meter (m), the electric field strength measured from two-way radios and cell phones ranged from 7–15 volts/meter (V/m) and 3–5 V/m respectively, depending on their maximum output powers and operating frequencies. The two-way FRS systems produced less electric field strength than cell phones. At a distance of 1 m, electric field strengths of 2–2.5 V/m were measured. A wireless LAN system generated an electric-field strength of about 0.1 V/m at a distance of 1 m from the antenna on the system (Lucas et al., 1994).

Figure 62-1 Electric field intensity measurement of wireless telecommunication devices.

Security Systems

Figure 62-2 shows the magnetic field strengths measured from three EAS systems, six WTMDs and 13 HHMDs. Two of the three EAS systems generated fields stronger than any metal detectors, approximately 1–5 Gauss. Walk-through metal detectors generated stronger magnetic fields than hand-held metal detectors. When compared to the Canadian Safety Code No. 18 for metal detectors (HWC, 1977), all metal detectors tested complied with the existing safety code.

Medical Devices Testing

Methodology for the Susceptibility of Medical Devices to EMI from Wireless Telecommunication Devices

Portable medical devices were tested in a vacant hospital room, while permanently mounted devices were tested on-site. Normal operating conditions for each device applied. Four models of analog cell phones with maximum power of 0.6 watts (W) and four models of two-way radios varying from 2–5 W were tested. The susceptibility of the medical device to EMI from wireless telecommunication devices was tested at a distance of 3 m. If EMI was not observed, testing was repeated at shorter distances until an effect was observed or until the telecommunication device was within 2 cm of the medical device. If EMI was observed, the distance was moved back until no effect occurred. At each distance, tests were done, first with the antenna in a vertical position and at different heights ranging from ground level to the height of the medical device. All tests were repeated with the antenna in a horizontal position and at the back, top, and both sides of the medical device. All distances were measured parallel to the ground, from the base of the antenna on the telecommunication device to the face of the medical device. After each test, the medical device was checked to confirm that it had not been permanently damaged or reprogrammed by EMI. Any observation was repeated at least three times to rule out coincidence. If it appeared that the effect changed over time (e.g., fluctuating values), the transmitting time was extended to determine whether the effect would increase, disappear, or remain within certain boundaries. A similar test procedure was incorporated into an American National Standards Institute (ANSI) recommended practice guideline (1997).

Results of EMI Testing

Wireless Telecommunication System

The results of EMI testing are shown in Table 62-1. The most obvious result is that more than 60% of the medical devices tested were affected by the presence of a wireless telecommunication device. Of these, 64% (32 of 50) were affected by two-way radios and 26% (13 of 50) were affected by analog cell phones. The two-way radios caused the greatest interference at the largest distances. The cell phones had a much smaller effect, which often occurred only at very close distances. Two-way radios caused some devices to malfunction at distances of 3 meters, while analog cellular phones did not cause malfunction at distances greater than 1 meter.

To qualitatively and quantitatively characterize the EMI-induced medical device malfunctions, each effect was assigned one of the following fault codes:

- Visible and/or audible alarm with device stoppage
- Visible and/or audible alarm with no device stoppage
- Readout errors with no change in operation
- Measured readout variation causing change in device operation

Figure 62-2 Magnetic field strength vs. frequency of electronic article surveillance systems and hand-held and walk-through metal detectors.

- E. Audio indicator distortion
- F. Device reboots or powers down by itself
- G. Loss of input being measured
- H. Distortion present in device measurement display (waveforms)
- I. Device malfunction, no alarms
- J. Display malfunction
- K. Device needed to be manually reset to continue proper operation
- L. Device changes operating mode
- M. Recorder malfunction
- N. Alarm malfunction
- O. No observed effect
- P. Device could not be approached from that direction

Figure 62-3 summarizes the percentage distribution of each fault code. The most common faults were readout errors with no change in operation (C), measured readout variation causing change in device operation (D), and device rebooting or powering-down by itself (F).

Figure 62-4 shows the results obtained at different distances. At any given distance, two-way radios caused more malfunctions and more severe malfunctions than analog cell phones. At distances less than 30 cm, two-way radios operating at 810 MHz caused more malfunctions than those operating at 165 MHz, 460 MHz and 818 MHz. Two-way radios operating at 165 MHz and 460 MHz caused malfunctions at distances greater than 3 m while the other radios had no effect. Analog cell phones did not cause malfunctions at distances greater than 1 m.

Table 62-1 shows that the wireless telecommunication devices interfered with the operation of the majority of medical devices. However, some of the devices showed an effect only at very close distances and specific frequencies.

The severity of EMI effects depended on the following factors:

- Distance from the wireless telecommunication device to the medical device
- Distance from the wireless telecommunication device to the transmission tower base station that determines the power output of the wireless telecommunication device

Table 62-1 Effects of Wireless Telecommunication Devices on Medical Devices

	Two-way radios				Cell phones	
	165	460	810	818	828	846
Frequency (MHz)	165	460	810	818	828	846
Power (W)	5	4	2.5	2	0.6	0.6
Electric field strength measured at 1 m from the dipole antenna	7	15	11	10	5	5
# of Medical Devices Tested			50			
# of Medical Devices Malfunctioned		32				18

Distances (m)	Number of Malfunctions					Total
	< 0.3	0.3-1.0	1.0-3.0	3.0-5.0	> 5.0	
< 0.3	26	32	39	34	19	150
0.3-1.0	7	17	10	13	4	51
1.0-3.0	10	9	5	3	0	27
3.0-5.0	2	4	0	0	0	6
> 5.0	1	1	0	0	0	2
Total	46	63	54	50	23	236

- Frequency of the wireless telecommunication device;
- Transmitting time, in some cases
- Shielding of the medical device and cables

These test results implied that cell phones caused a larger effect when initially transmitting a call. Once the connection was established, the severity of the effect often diminished slightly. The reason could be that cell phones adjust their power outputs depending on the distance from the operating site to the base station.

To analyze the EMI risk, all observed malfunctions were categorized into five classes (lowest risk to highest risk):

- I Change in output (e.g., distortion of waveform) but operation of device and safety of patient is unaffected
- II Transient error message display, no reset of device required
- III False output readings, which may affect treatment of patient
- IV Error message display, manual reset of device required
- V Operation of device is affected, but there is no visual indication.

Figure 62-5 shows the distribution of malfunctions by risk category obtained with the five wireless telecommunication devices. The analog cell phones, which had lower power outputs than the two-way radios, produced fewer device malfunctions than the radios. The 165 MHz and 818 MHz two-way radios generated fewer device malfunctions than the 460 MHz and 810 MHz radios. Of all the malfunctions, 29% were Class IV and V (the two higher risk categories). Of these, 28% were caused by two-way radios, while 1% was caused by the analog cell phones.

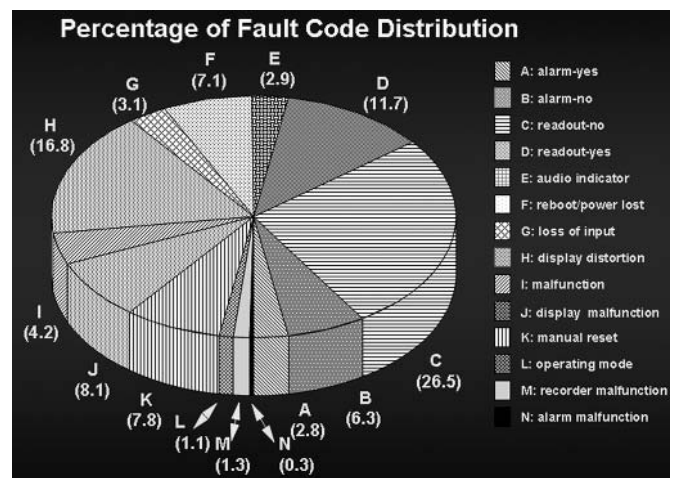

Figure 62-3 Percentage fault code distribution.

Distribution of Fault Codes

Figure 62-4 Distribution of fault codes.

Figure 62-6 Susceptibility tests of six medical devices.

The authors tested 106 medical devices located throughout one 300-bed and two 800- to 900-bed hospitals in Canada to assess their susceptibility to EMI from two wireless LAN systems and one medical telemetry system (Tan and Hinberg, 2000a). When the wireless LAN system was in standby mode and within 10 cm of three models of hand-held ultrasound Doppler heartbeat detectors, the Doppler units produced periodic high-pitched beating sounds, which could be misinterpreted as normal heartbeat sounds from a patient. The periodic sounds changed to random static noise when the wireless LAN system was transmitting data. In addition, the quality of the data transmission from the wireless LAN system and its base station deteriorated in the colonoscopy room, possibly because the room was lead-shielded. A hard-wired connection from the wireless LAN would prevent deterioration of transmission quality. None of the devices was affected by a medical telemetry system operating at 466 MHz. This study indicated that a wireless LAN system, employing very low field intensities, could be used safely in close proximity to medical devices.

FRS Two-Way Radio Systems

Two models of FRS systems, operated at 461.8 MHz and 467.8 MHz, could cause malfunctions on four out of seven models of infusion pumps from four manufacturers. All four pumps either prompted an occluded message, that would require the operator to push the flow button to continue, or a failure message, that would require the operator to reset all settings. The interference occurred when the FRS two-way radio was about 10 cm closer to the pump. FRS systems also caused one model of infant incubator to increase its temperature display readings from nearly 50 cm away. The heating circuitry was affected and would not turn on the heater to maintain the incubator's preset temperature. In addition, FRS systems affected the trace display of two models of electrocardiograph monitors. These observed malfunctions were similar to the regular two-way radios or cell phones, both of which had higher power than FRS systems. FRS systems did not interfere with the two models of external defibrillators or two models of pulse oximeters tested.

Implantable Cardiac Device Testing

Methodology for *In Vitro* Testing

The setup for testing the susceptibility of implantable cardiac pacemakers to EMI included a human torso simulator (Tan and Hinberg, 1998). The simulator consisted of a plastic box filled with 0.18% saline solution (0.03 M). The plastic box was placed horizontally on top of a table to test wireless telecommunication devices and vertically on a table with moving wheels to test electronic security systems. The pacemaker and its leads were mounted on a grate and totally submerged in saline. The leads formed a semi-circle with a diameter of about 20 cm in the shape of a brass clef, and were fastened onto a grate. Figure 62-7 shows the schematic diagram of the experimental setup. Two stainless steel plates were used to monitor the electrical activity of a pacemaker. Signals obtained from these plates were amplified with a differential amplifier and the signal from the amplifier was displayed on a storage oscilloscope. Simulated electrocardiography (ECG) signals from a patient simulator were displayed on an ECG monitor. The amplified ECG signals from the monitor were applied to two other stainless steel plates that were mounted perpendicular to the first two and used to apply simulated ECG signals that would inhibit the pacemaker. Implantable defibrillators were tested with the same setup.

Inhibition

Any changes in the pacing signals, such as the amplitude and the pulse duration of the pacing signals, the pacing intervals between the atrial and ventricular pulses, and the pacing frequency, were recorded. This was done to determine whether the signal from the radiofrequency sources could cause the pacing outputs to induce a total, partial, or prolonged inhibition.

Figure 62-5 Malfunctions by risk category.

Since some medical devices showed an effect only at short distances from the telecommunication devices and only at specific frequencies, the researchers conducted susceptibility tests for a selected number of medical devices. Figure 62-6 shows EMI susceptibility curves for the six medical devices that were the most susceptible to EMI from wireless telecommunication devices. Four of the devices failed to meet the current International Electrotechnical Commission (IEC) electromagnetic compatibility (EMC) requirements of 3 V/m (IEC, 1993).

The results indicate that cell phones create a greater EMI effect when establishing a connection. Once the connection has been established, the severity of the effect often diminishes. The reason could be that cell phones adjust their power outputs depending on the distance from the operating site to the base station.

These results are generally consistent with the ad hoc testing results reported by other investigators (Segal et al., 1996; Tan and Hinberg, 1995a; Tan and Hinberg, 1995b; Rice et al., 1993; Malach, 1993; Lange, 1993; Bostrom, 1991; Tan and Hinberg, 1995c; Baba et al., 1998; Hietanen et al., 2000). Segal et al. (1996) found that two-ways radios caused malfunctions in 50-70% of medical devices tested. One device malfunctioned when the two-way radio was 3 m away. Baba et al. (1998) reported that 53% of medical devices (57 of 108) were affected by cell phones with maximum power of 0.6 W-0.8 W and concluded that these effects were low-risk. A low-power personal hand-held phone with a maximum output power of 0.08 W interfered with only 4% of the devices. Hietanen et al. (2000) studied the effects of cell phones on 23 medical devices in one hospital and concluded that GSM 1800 MHz phones were safe for use in hospitals, while GSM 900 and NMT900 phones should be restricted to areas with no sensitive medical devices.

Wireless LAN and Medical Telemetry Systems

A wireless LAN system operating at 2.42 GHz generated an electrical-field strength of 0.1 V/m at 1 m from the antenna of the system. The background electrical field strengths at each test site were below 0.1 V/m, except near the corridor of the elevator outside the operating rooms, where the electrical field strength varied from 0.15 V/m-0.25 V/m.

Figure 62-7 Experimental setup for studying EMI effects from radiofrequency sources on implantable cardiac pacemakers.

Reactivation

After the threshold amplitude of the amplified ECG signal was established, the output amplitude of the amplified ECG signal was set to twice its threshold amplitude. The effect could be to change the pacemaker's operating mode to an asynchronous mode with a rate different from the simulated ECG signals, or to a rate synchronous with the pacing frequency of the simulated ECG signal. When the reactivation took place, the pattern of pacing, either regular or irregular, was recorded to determine whether EMI could reactivate the pacing signal of the pacemaker after it had been inhibited by the simulated ECG signal.

Wireless Telecommunication Devices

Each wireless telecommunication device was tested at different points on the grate with the antenna of the wireless device oriented either parallel or perpendicular to the long axis of the simulator. In the case of the analog and digital cellular phones, and FRS systems, actual communications were carried out either by keying out or calling in to the wireless device. Only keyed-out communication was programmed for the PCS system.

Walk-Through Security Systems: Static and Dynamic Tests

The simulator was placed on a turntable mounted on a wooden table with rigid rubber wheels. The header of the pacemaker was 122 cm above the ground. Static tests simulated a person standing with his shoulder against the transmission panel of a security system (perpendicular orientation), or with his back against the panel (parallel orientation) by turning the turntable 90° (see Figures 62-8 and 62-9). Tests for inhibition and reactivation were conducted at various locations along the transmission panel and various turntable angles. Dynamic tests were conducted by slowly rolling the wooden table at a speed of 20 cm/s to simulate a person slowly walking through the security system. Tests were repeated for the parallel orientation with the front surface of the simulator placed parallel to the transmission panel of the security system.

Linear Positioning

For the parallel orientation, the surface of the simulator was kept parallel to the surface of the transmission panel of the security system. (See Figure 62-8.) The distance from the surface of the security system transmission panel to the header of the pacemaker was set between 8.5 and 9.4 cm to keep the distance from the mid-point of the panel to the header of the pacemaker at about 11 cm, since the thickness of the panel of the security systems varied. Figure 62-6 shows the orientations and locations relative to the EAS panel.

For the perpendicular orientation, the turntable holding the simulator was rotated 90 degrees perpendicular to the transmission panel. (See Figure 62-9.) The distance from

the surface of the transmission panel to the header of the pacemaker was 12 cm. Both inhibition and reactivation tests were conducted at 5 cm intervals along the transmission panel, with the last interval varied because the width of each security system changed. Tests were repeated by rotating the turntable 90 degrees in the other direction perpendicular to the transmission panel. The distance from the surface of the transmission panel to the header of the pacemaker was changed to 23 cm. This was done to simulate a person with an implantable pacemaker at 12 cm and 23 cm from the transmission panel of the security system when the person walked through the system in opposite directions and touched the transmission panel while walking. The locus for the header of the pacemaker formed a parabolic curve with various distances from the transmission panel of the security system.

Rotation

Additional tests were carried out with the header of the pacemaker 122 cm from the ground, by rotating the torso simulator at 15-degree intervals until the simulator was perpendicular to the transmission panel. (Figure 62-9.) The simulator was kept at each position for 10 seconds. Inhibition and reactivation tests were performed for each position at three locations: at the middle and at both ends of the panel.

Hand-Held Metal Detectors

The HHMD was slowly swept up and down five times in front of the simulator to simulate a pacemaker patient being searched by security personnel. Three models of EAS systems from two manufacturers were tested. Six WTMDs from three manufacturers and 13 HHMDs from nine manufacturers were also tested.

Results of *In Vitro* Testing

Wireless Telecommunication Systems

Nine of the 20 pacemakers tested were susceptible to EMI from nearby digital cellular phones (Barbaro, 1995). Interference effects were generally not observed when the cell phone was more than 15 cm from the pacemaker. (See Figure 62-7.) Dual-chamber (DC) pacemakers were more susceptible to interference than single-chamber (SC) models. All four models of digital cell phones used in the tests decreased the output pulse rate of two SC pacemakers and two DC pacemakers. All four phones also induced rhythmic pacing in three SC pacemakers and four DC pacemakers when the output pacing of the pacemaker was inhibited by an external ECG signal. There was a ten-fold increase in the monitoring peak amplitudes of the pacing output from one SC pacemaker and one DC

Figure 62-8 Orientations for the testing of security systems on cardiac pacemakers.

pacemaker from the same manufacturer. The 3.4% rate of interference is consistent with the results reported in other *in vitro* and *in vivo* studies. (See Table 62-2.) The EMI generated by the wireless devices did not reprogram the pacemakers. The interference effects ceased when the phones were turned off, and the pacemakers returned to their normal operations. Analog cell phones, digital PCS systems, and FRS systems did not cause any interference with pacemakers. These findings suggest that pacemaker-dependent patients should use analog or PCS phone systems. This is consistent with the findings by Hayes et al. (1997) that analog cellular phones are safe for patients who have pacemakers.

The study showed that some pacemaker designs appeared to be immune to EMI. Two models of DC pacemaker, with and without filters, were tested to investigate the effectiveness of filtering circuitry. No EMI effects were observed in the model with filters, and transient inhibition was observed in the model without filters. A clinical study by Carillo et al. (1996) confirmed that there were no interference effects on pacemakers with filters. These findings suggest that improvements in filtering technology to reduce the susceptibility of pacemakers to radiofrequency EMI should be encouraged.

To determine the vertical distances needed to induce EMI effects between the wireless system and a pacemaker, additional testing was done on the pacemakers found to be susceptible to EMI. A digital cellular phone was placed on wooden blocks above the grate of the simulator and the distance was measured when an inhibition or a reactivation was observed. Figure 62-10 shows the average 3-D EMI effects on nine pacemakers. The average maximum vertical distance at which interference was observed was 3.4 cm above the pacemaker. However, in one case interference was observed at a distance of 40 cm from the pacemaker. In all cases, EMI occurred only when the phone was in the transmission mode.

In the test of FRS two-way radio systems, 21 out of 22 models of cardiac pacemakers and two models of implantable defibrillators were not affected. FRS systems caused one model of dual-chamber cardiac pacemakers to increase the pacing amplitude by 1.5-fold and keep the same pacing frequency. When the FRS transmission stopped, the interference diminished.

Two wireless LAN systems were tested in close proximity of 22 models of cardiac pacemakers and two models of implantable defibrillators; none of the pacemakers or defibrillators was affected.

Electronic Article Surveillance Systems

The authors also studied the susceptibility of 22 pacemakers and two implantable defibrillators to EMI from three types of EAS systems: Pulsed magnetic field (UM), continuous magnetic field (SM), and sweep-frequency magnetic field (CS) (Tan and Hinberg, 1998 and 1999). During static tests, UM systems decreased the electrical output pulses of

eight of the pacemaker models, while SM systems affected five pacemaker models, and CS systems did not affect any pacemakers (Table 62-3). The decrease in the pacing frequencies of some pacemakers may be of concern to patients who are fully dependent on their pacemakers. Pacemaker-dependent patients may experience dizziness or collapse if pacing ceases for more than 3 seconds. When the output of the pacemaker was inhibited by an external ECG signal, UM systems induced rhythmic pacing on 15 pacemakers at distances up to 33 cm from the transmission panel, while SM systems affected 12 pacemakers, at distance up to 18 cm. This asynchronous pacing could compete with the normal sinus rhythm to induce arrhythmia. Dodinot et al. (1993) and Lucas et al. (1994) reported

Figure 62-9 Linear and rotation modes for the testing of security systems on cardiac pacemakers.

Table 62-2 Effects of Various Wireless Telecommunication Devices on Pacemakers: *In Vitro* and *In Vivo* Studies

Zero indicates no interference.

interference effects from other EAS systems. In addition, the bipolar lead configuration appeared to be less susceptible to interference from SM systems than the unipolar lead configuration. This finding is consistent with those of Dodinot et al. (1993) and Lucas et al. (1994). Furthermore, the same EMI effects occurred inside and outside the transmission panels of the EAS gate. There was no interference when the simulator was rolled through any EAS system during the dynamic tests. The two defibrillators were also unaffected by any EAS systems. However, McIvor (1995) and Mathew et al. (1997) have reported that patients with implantable defibrillators experienced inappropriate firing while in close proximity to an EAS system. None of the EAS systems caused any permanent damage or reprogramming to the pacemakers and defibrillators. These findings suggest that pacemaker patients should not stop within 33 cm of either side of the transmission panel of an EAS.

Walk-Through and Hand-Held Metal Detectors

None of the 13 HHMDs interfered with the 22 pacemakers and the two implantable defibrillators tested (Hayes et al., 1996). One WTMD decreased the pacing frequencies of five SC and three DC pacemakers during the inhibition tests, and 10 SC and four DC paces

makers induced reactivation. The other five WTMDs caused interference with only two SC pacemakers during inhibition and reactivation tests. No interference was observed when the simulator was rolled through the WTMDs during the dynamic tests. These findings indicate that WTMDs may affect some pacemaker models if the patient remains near the detector for longer than 2 seconds. However, these findings are not consistent with the report by Copperman et al. (1988) that WTMDs have no effect on implanted pacemakers. None of the WTMDs interfered with the implantable defibrillators except for one model of WTMD, which stopped defibrillation on one model of defibrillator when a ventricular fibrillation was simulated. In no case did the WTMDs or HHMDs cause reprogramming or permanent damage to any pacemakers or defibrillators. Asch et al. (1997) reported that airport security could affect cardiac pacemakers and other implanted metallic devices. These studies suggest that pacemaker and defibrillator patients should not stop within 33 cm of either side of the transmission panel of the WTMDs.

Discussion

Although many device manufacturers have addressed EMC, there still appears to be insufficient awareness of EMI problems. The need to educate users, manufacturers, and regulators about EMI and to develop EMC standards persists. Preventing all EMI malfunctions is difficult given the challenge of making medical devices immune to all sources of EMI. The exposure to an EM environment, and the frequency, location, orientation, and design of a device can influence whether and how a device will be affected by EMI. In practice, it is impossible to completely stop EM energy at its source. Modern society has become too dependent on the convenience of instant communication. Some medical devices themselves often emit EM energy, and simultaneous use of several medical devices in a hospital room can also cause EMI problems.

All ad hoc studies of EMI susceptibility of medical devices have consistently reported that wireless telecommunication devices can cause a high percentage of medical devices to malfunction. In contrast, a relatively small number of EMI incidents have been reported to regulatory agencies in Canada and the United States. Under-reporting may be due to a lack of awareness of EMI as the cause of device malfunction. Based on the studies mentioned above, researchers (Tan et al., 1995; Siegel et al., 1996) have suggested that hospitals should develop policies for handling the use of any wireless telecommunication devices. Participants in the Round Table on EMC convened by Health Canada in September 1994 unanimously agreed that cell phones should not be banned in hospitals, but that policies should be established to govern their use (Tan et al., 1995).

The results presented here confirm that the very low field intensities generated by wireless LAN systems do not interfere with medical devices in the hospital. These findings sug-

Figure 62-10 3-D spatial effects from digital cellular phone on pacemakers.

Table 62-3 Effects of security systems on pacemakers

Type	Mode	Carrier frequency	Magnetic field strength (ΦT) [*]	Effects on pacemakers	
				Inhibition	Reactivation
EAS	Continuous	535 Hz	450	23 %	55 %
	Modulated pulse	Carrier: 58.4 KHz modulation: 60 Hz	400	36 %	68 %
	Sweep	7.4-9.1 MHz	0.1	0	0
WTMD	Repetitive pulse	250-500 Hz	4.5 -10	5 %	9 %
	Repetitive pulse	89 Hz	45	36 %	64 %
	Modulated Pulse	250 -909 Hz	18 -22	5 %	9 %
	Modulated pulse	210 Hz	12	9 %	14 %
HHMD	Continuous	14 kHz -1.8 MHz	0.2 -10	0	0

*Measured at 15 cm from the transmission panel of EAS and WTMD systems, and 2.5 cm from HHMDs; zero indicates no interference effects.

gest that these wireless systems are acceptable for use in hospitals in view of the benefits of obtaining real-time access to patient medical information. Nevertheless, hospitals should test each new wireless communication system on potentially susceptible devices before putting them into general use. One of the conclusions of the Canadian Task Force on EMC in Health Care, established in 1994 after the Round Table Discussion on EMC in Health Care (Tan et al., 1995), was that "the potential for EMI is minimized by using RF sources having the lowest possible transmission power" (Siegel et al., 1996). The task force recommended replacing high-power sources with low-power ones. The findings described in this chapter support the use of low-power wireless communication devices in hospitals.

Furthermore, these studies confirm that EMI from nearby digital cellular phones may affect the operation of some implanted cardiac pacemakers under worst-case conditions. The greatest risk of interference occurs when the antenna of the phone is in close proximity to the pacemaker. The resulting decrease in the frequencies of the output pulses or transient responses of some pacemakers may be of concern to patients who are fully dependent on their pacemakers. The unwanted rhythmic pacing induced in some pacemakers during reactivation is a concern, since it could compete with the normal sinus rhythm of the heart and induce arrhythmia. In all cases that produced EMI effects, if the phone is in stand-by mode and is placed in close proximity to the pacemaker, an incoming call will switch the phone to its transmission mode and may interfere with the pacemaker. When the phone is turned off, the interference stops, and the pacemaker resumes its normal operation.

EMI did not occur with the analog cellular phone or the PCS system, probably because of the low power output of these communication devices. These findings suggest that pacemaker-dependent patients should use an analog cellular phone or a PCS system.

Strategies to Reduce EMI Risk

Managing EM Fields Within and Outside Hospitals

Hospital administrators and biomedical engineers or clinical engineers should understand radiofrequency and its sources. Hospital administrators should consider developing hospital policies for controlled use of radiofrequency sources and the frequency spectrum. Administrators should also consider integrating radiofrequency sources and systems with their existing communication systems to eliminate any uncontrolled communication sources in hospitals.

Managing Medical Device Immunity

Hospital administrators and clinical and technical staff should be educated about EMI-related risk. It is important for biomedical engineers, clinicians, and nurses to be aware of EMI-related incidents and report those incidents to the correct authority. If any staff member finds any sensitive medical devices susceptible to EMI, they should relocate them or separate them. Biomedical or clinical engineers should determine the immunities of their life-support and critical care medical devices. Due to financial constraints, many hospitals continue to use older medical devices that were not designed or tested for electromagnetic compatibility. Biomedical and clinical engineers should advise hospital administration that all medical devices considered for purchase must at least comply with existing EMC standards.

Hospital Policies

ECRI recommends against the use of mobile telephones or hand-held radio transmitters (walkie-talkies) in health care institutions because of the potential for their interference with the safe operation of life-support or critical monitoring equipment (ECRI, 1993).

The Regina Health Board has prohibited the use of cellular phones and other transmitting devices in certain areas of hospitals (Regina Leader-Post, 1993). The Royal Alexandra Hospital in Edmonton has a policy that only emergency service personnel who require constant communication during emergency situations, may use their cellular phones and portable two-way radios in patient rooms and critical patient care areas. These telecommunication devices must be used as far away from any nearby medical devices as possible (e.g., 3–4 m). If possible, users of portable two-way radios should leave the patient area to make the transmission. The policy also requires signs at all public entrances to the hospital to warn visitors to turn off cellular phones or two-way radios, and signs at all entrances to critical care areas to restrict the use of cellular phones and two-way radios. Individuals who need to use cellular phones and two-way radios are advised to use them in places where medical equipment is not used, such as lounges, waiting rooms, offices, and cafeterias.

Many hospitals in Scandinavian countries have prohibited the use of mobile telephones (and radio transmitters) within the entire hospital area (Bostrom, 1991). Some hospitals prohibit the use of mobile telephones within certain distances (e.g., 8 m) from a medical device.

Section 5.3.6 of the Canadian Standards Association (CSA) publication CAN/CSA Z32.2-M89, "Electrical Safety in Patient Care Areas" (CSA, 1989), states that "Patient-owned radio transmitters of any kind, (e.g. citizen band radios, walkie-talkies, portable or cellular telephones, amateur radios, etc) should not be permitted in or near intermediate and critical care areas."

Recommendations for Implantable Cardiac Devices

The chances that EMI from digital cellular phones would produce life-threatening situations are low. However, data presented here support the recommendations in the Health Protection Branch's Medical Device Alert No. 108 (MDA, 1995) that cautions patients with pacemakers as follows:

1. The use of a digital cellular phone very close to the pacemaker may cause the pacemaker to malfunction.
2. It is advisable to avoid carrying the cellular phone in a breast pocket directly over the pacemaker because an incoming call will switch the phone to its transmission mode and may cause interference.
3. In using a cellular phone, patients should hold it to the ear farthest from the pacemaker.

Wireless Technology Research (WTR) and the Health Industry Manufacturers Association (HIMA) Pacemaker Interest Group recommend 15 cm as an adequate separation distance between a pacemaker and a wireless phone (WTR, 1996). This distance appears to be valid for minimum risk with most pacemaker designs.

Interference with pacemakers by security systems such as EAS systems and WTMDs may pose a potential risk, depending on the model of pacemaker, the programmed mode, and the type of the security system. The greatest risk of interference occurs when the pacemaker is close to the security system and the individual is stationary. This condition is unlikely to be encountered during normal exposure to an EAS system or walk-through metal detector, since pacemaker patients do not remain stationary within these systems.

Interference with pacemakers occurs on both sides of the transmission panel of an EAS system or a walk-through metal detector and at distances as far as 33 cm for UM, 18 cm for SM and 33 cm from WTMDs. Patients may incorrectly assume that EMI effects occur only when they are inside the gate. Data described in this chapter suggest that pacemaker patients should not stop and linger within 33 cm of either side of the transmission panel as measured from the patient's shoulder to the transmission panel of the security system. Instead, they should walk through the system at a normal pace without stopping. Manufacturers should consider placing a sign on the transmission panel to identify the presence of a security system and advise pacemaker and defibrillator patients to walk through the system at a normal pace. In addition, EAS systems should not be installed in the vicinity of cash registers in such a way that pacemaker-dependent patients must stand within 33 cm of the EAS system while completing their transactions.

EMI Awareness

Many EMI malfunctions could be prevented through education. Health Canada places a high priority on providing information to the public. *Medical Device Alert* and *It's Your Health* bulletins are sent to health care professionals to warn them of problems and provide recommendations for management of the associated risks (Tan and Hinberg, 2000b). Health Canada scientists have also published scientific papers on EMI and have given many lectures on the topic at scientific conferences and workshops (Tan et al., 1995; Tan and Hinberg, 1999; Tan and Hinberg, 1995a; Tan and Hinberg, 1995b; Tan and Hinberg, 1995c; Tan and Hinberg, 2000b).

Electromagnetic Compatibility (EMC) Standards

The U.S. FDA issued a voluntary standard MDS-201-0004 in 1979 specifying that radiated immunity of medical electrical equipment should be 7 V/m from 450 MHz to 1000 MHz. The international collateral standard IEC 60601-1-2 on electromagnetic compatibility for medical electrical equipment states that an immunity of 3 V/m shall apply for the frequency range from 26 MHz to 1000 MHz. However, a higher level of immunity was proposed in recognition of risks to life-support equipment. The draft second edition

of the IEC 60601-1-2 proposes 10 V/m for life-support equipment and 3 V/m for other medical electrical equipment for the frequency range from 80 MHz to 2.4 GHz. However, immunity of 10 V/m does not guarantee that EMI effects will not occur. In addition, IEC 60601-1-2 (1st edition) requires testing with 1 kHz amplitude modulation at a single modulation frequency. The draft 2nd edition proposes testing at 80% amplitude modulation at 2 Hz if the physiological simulation frequency and operating frequency of the medical device under test is less than 1 Hz or greater than 3 Hz, and it is no longer required to test at 1 kHz.

The need for establishing specific EMC standards for medical electrical equipment and systems is well recognized. Designing medical devices to be immune to electromagnetic fields up to 10 V/m for life-support medical electrical equipment and 3 V/m for non-life-support medical electrical equipment, as proposed in international standards, would greatly reduce the hazard from EMI. The ISO TC150SC6 Working Groups 1 and 2 are drafting specific EMC standards for implantable cardiac pacemakers and defibrillators.

Conclusion

In conclusion, management of the use of radiofrequency sources and attention to the electromagnetic compatibility of medical devices in health care facilities will provide some assurance as to the safe use of medical devices and may prevent EMI problems.

James Hibbetts

Texas Children's Hospital
Houston, TX

The density of occupancy of the electromagnetic spectrum is increasing because of the expansion of wireless services (the culprits). Despite the efforts of manufacturers to harden clinical devices to the effects of electromagnetic interference (EMI), reports of new incidents of interference to previously unaffected medical devices (the victims) appear in medical literature and anecdotally (CBS, 1994; Paperman et al, 1994). The role and the knowledge base of the clinical engineer must expand to understand and manage these ever-increasing challenges.

Electromagnetic Radiation

Electromagnetic radiation occurs when an alternating current is generated. An electromagnetic field is created in the vicinity of the source. The range, or distance of the radiated electromagnetic field can be increased when coupled to a conductor. The magnetic field is further radiated by the flow of the current along this conductor. Even at a reduced amplitude, a corresponding current will be generated when another conductor is subjected to the field of the radiating conductor. The radiated field will have many characteristics. The most important of those characteristics are amplitude, periodicity, and waveform.

The amplitude of the impressed alternating current defines the energy of a radiated field. This field is generally expressed in volts per meter (V/M). Amplitude at the source point (transmitting conductor) will define, in conjunction with frequency and distance, the amplitude of the electromagnetic field induced in the secondary (receiving) conductor subject to the Inverse Square Law.

The periodicity or frequency of alternation is expressed in Hertz per second, which allows the calculation of the wavelength of the radiated electromagnetic field. Knowing the wavelength versus the physical length of both the radiator and the secondary conductor into which the radiated energy is induced provides an estimate of the potential amplitude developed by or within a device at risk. Waveforms other than linear (sinusoidal) can produce multiple and variable frequencies. The foremost example of a nonlinear waveform is the square wave. The square wave produces many multiples, or harmonics, which have a range many times that of the fundamental frequency. The majority of digital devices generate square waves.

Depending on the amplitude at the point of generation, the efficiency of the auxiliary radiator (antenna), the generated frequency, and the waveform, the potential for interference between digital devices and clinical devices can exist for many kilometers from the source of electromagnetic radiation.

EMI threats come from a multitude of sources. These are broadly divided into two categories: Devices that emit intentional electromagnetic radiation for communications and control, and devices that, as a byproduct of their operation, emit unintentional (incidental) radiation (Figure 63-1). Some of the major and more common sources of EMI encountered in the clinical environment follow.

Intentional Radiators:

- Television broadcast stations: Analog and digital
- Commercial radio stations: Analog and digital
- Land mobile radio: Fixed base (FB), mobile, and portable two-way radio sources (walkie talkies)*
- Paging: One-way and two-way wireless messaging service transmitters
- Cellular telephones and sites*

- Wireless personal digital assistants (PDAs)
- Wireless networking devices (an increasing threat in the 2.4 GHz industrial, scientific, and medical ISM band)
- Unlicensed and unauthorized users of two-way radio communications equipment (Pirates)*

Unintentional Radiators:

- Lighting systems (especially florescent), including energy saving electronic ballasts*
- High energy control systems (HVAC controllers), especially variable-speed controllers*
- Malfunctioning electrical services*
- Universal-type electric motors*
- Pulse oximeters*
- Displays (CRT and plasma), computer, television, and instrumentation
- Wired computing networks
- "Smart" fire detection and alarm devices*
- Electrosurgical units (ESU)*
- Defibrillators

These sources of electromagnetic radiation, as seen from the previous lists, can be intentional or unintentional. The challenges and the institutional responses imposed by the presence of these EMI sources can be divided, for all intents and purposes, into four parts: Mitigation, detection, correction, and prevention. Although the mitigation and prevention phases appear to be similar, they differ in their approaches and applications.

Controlling the Effect of EMI

Mitigation

In the mitigation phase, the principal concern is reducing risk to, or victimization of, clinical devices by devices emitting unintentional or intentional electromagnetic radiation. The sources of the devices may be internal or external to the institution. The devices may be intentional or unintentional radiators of electromagnetic fields, and the electromagnetic energy may be radiated or conducted. Figure 63-1 illustrates the electromagnetic interaction among intentional and unintentional radiators and intentional and unintentional targets.

Mitigation is accomplished in part by the careful analysis of a device, including the accessories to be used with it, and the electromagnetic environment in which it will be used. A successful approach has been implemented at Texas Children's Hospital. This approach is accomplished in two phases: Thorough analysis of the environment in which the device is to be placed, called "footprinting," and an equally thorough analysis of the clinical device itself, called "fingerprinting." The procedures of quantifying potential EMI and mitigating the effects through environment analysis are described in greater detail later in this chapter.

* Sources (the culprits) of incidents attributed to EMI encountered at Texas Children's Hospital

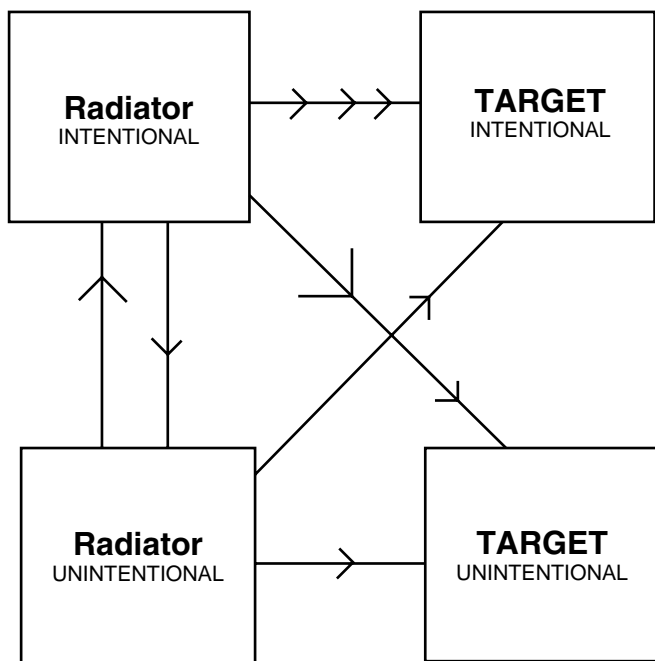

Figure 63-1 The complexities of EMI-radiators and targets: Culprits and victims.

Another vital part of the mitigation process occurs during facility planning. Whether planning a new facility, an expansion of an existing facility, or remodeling of a facility, clear and concise communications between affected departments, architects, contractors, and the clinical engineering department are vital at all stages of the project. For example, one institution installed expensive, screened rooms at great cost. When the clinical engineer, acting on complaints of erratic EMG operation, determined that the room played a role in the culprit/victim relationship, the rooms were disassembled, also at great cost. In this case, the relocation of the affected department was not an option. The clinical engineering department had not been made aware of these rooms, or of their intended application that involved the use of known culprit devices.

Examples of proactive mitigation include consulting services provided by the Biomedical Engineering Department and the Television Services Group during the latest expansion of Texas Children's Hospital. These services, which involved the expertise of all groups within the biomedical engineering department, included not only space design, but the design, implementation, and expansion of wireless paging and communications systems. Through the use of a distributed energy antenna systems, (i.e., leaky coax-radial) radio frequency power levels were maintained at levels deemed safe for clinical devices while providing the required coverage area for a nurse call-specific paging system. Safe wireless telephonic communications were implemented using low-power microcellular systems. Infant abduction systems were reviewed for specifications including emission characteristics, and a system was selected based in part on its low electromagnetic radiation levels.

The use of portable radio communication devices in a large campus environment is a basic requirement for security, engineering, and guest services. As part of the mitigation process, instruction in the safe use of two-way radio equipment in the clinical environment is mandatory for all personnel who use this equipment (ECRI, 1993).

Detection

Detection is implemented upon the report of a device malfunction. A preliminary analysis of the incident may indicate that the cause of the malfunction, intermittent or permanent, may have been electromagnetic interference. In the case of continuing or continuous device malfunction not otherwise attributable to defects within the device itself (e.g., no problem found [NPF] service reports), a careful investigation begins, using various test equipment, some of which may require specialized construction. This section presents a more detailed description of the basic equipment necessary to locate and identify sources of EMI and some of the basic techniques, referred to as "ghost hunting." Once the type and source of the interference is detected and analyzed, the next step is to reduce or eliminate the interference to the victim device. However, the victim device is removed in some cases, because of an intensely hostile electromagnetic environment. Replacement of the victim device with an equivalent device that may have other, less sensitive responses is an option.

The detection phase can eliminate the possibility of electromagnetic interference as the culprit and cause of improper operation of a specific device. Indeed, subsequent investigation can reveal technical problems within a device that were previously attributed to electromagnetic interference.

Correction

Correction of victim/culprit relationship(s) can take many forms, some practical, some impractical. Correction may be part of a process to ensure that the victim device meets all specifications that can affect its susceptibility to electromagnetic radiation. For example,

hospital staff should ensure that proper case-to-case contact is made in coated conductive coatings and that the coatings have not been worn or abraded. In some instances, the victim device can and should be removed from the environment where it is at risk. If the culprit is local, removal may be one practical solution to the problem. Instances of electromagnetic radiation emanating from abandoned wiring (passive reradiation) have occurred that dictated removal of the wiring. Interference to clinical devices originating from active (nonfiber optic) wiring, such as networking trunk conduits, mandates rerouting of the wiring. The same can apply to modern in-plant telephone systems, usually digital in nature. Experiences at Texas Children's Hospital support the work of researchers (ECRI, 1988) in finding that shielded rooms rarely correct problems when the source of electromagnetic radiation is contained within the local environment. In extreme cases, the existing shielded room must be disassembled or the victim equipment (and department), moved to other quarters within the institution.

Prevention

Sustainable EMI prevention must include institution-wide compliance with guidelines and with those policies created within an institution to limit possible sources, EMI as well as the selection and deployment of medical devices that offer more effective immunity from EMI. Overall, observance of this two-pronged policy will have the effect of reducing the risk of electromagnetic interference to the proper operation of clinical devices and therefore reducing the risk to the institution. At Texas Children's Hospital, EMI prevention takes several forms (David, 1993). A proactive policies and procedures manual that, guided by the biomedical engineering department, defines allowable sources of radiation within the institution and mandates training procedures for employees of the institution that are required by job necessity to carry sources of electromagnetic radiation, i.e., intentional radiators. As an example, signage mandated by the policies and procedures manual directs that all cellular telephones be turned off. Their use within the institutional campus is not allowed. The policies and procedures manual further mandates that all employees using radio equipment, especially handheld devices, be trained in their safe use within the institution. Additionally, a stipulation that clinical devices must be EMI compatible is incorporated into the Condition of Sale, issued and agreed to by vendors, to define the technical conditions that must be met under the purchase contract.

Case Histories

Role Reversal

An unusual example occurred when the victim (i.e., a pager), normally considered a culprit (i.e., a physiological monitor), and the culprit, normally a victim, exchanged roles. Pagers had ceased receiving calls in a cardiovascular intensive care unit. Field intensity measurements, interrogation of employees, and other investigative procedures conducted by the clinical engineer yielded a scenario in which some pagers were not able to receive calls when near a well-known intensive care monitoring system.

Standards and practices relating to on-site testing for the presence of electromagnetic radiation were reviewed. A modified Open Antenna Test Site (OATS) procedure (ECRI, 1992; ECRI, 1988), was used as the measurement guideline (Bennett, 1993). As for equipment, an Empire NF-105 field intensity metering system (loaned by a staff member previously engaged in field site radio frequency [RF] measurements), was used as the measurement device. An area characterization (i.e., *footprint*) in the area of interest was taken as well as a characterization of a representative culprit device (i.e., *finger-print*). The field intensity measurements of a representative unit of the monitor system showed the existence of an unintentional radiofrequency close to the operating frequency of the paging system. Once the source of the EMI was identified, the results were presented to the manufacturer. Initial responses from the manufacturer's media representatives were not encouraging. During one conversation, the manufacturer's electromagnetic interference expert said that the solution was to increase the radiated power of the paging transmitters. This solution was immediately dismissed from consideration, because increasing the level of intentionally radiated electromagnetic energy to compensate for the effect of existing unintentional electromagnetic radiation would increase the potential for risk to other clinical devices. Only when the biomedical engineering department was ready to persuade the client department to cancel the purchase order for the remaining devices did the manufacturer discover a modification to reduce the severity of the interference. This modification, when installed, did not remove all of the unintentional radiation but did reduce the level of the interfering electromagnetic radiation sufficiently to relieve interference with pagers. The manufacturer essentially redistributed and dispersed the radiated energy to other points in the spectrum, which reduced the amplitude at the specific pager operating frequency.

This incident was an interesting introduction to the practical effects of device compatibility (or lack of) and electromagnetic interference in the clinical environment. After a technician from the Texas Children's Hospital Biomedical Engineering Department installed the modification provided by the manufacturer, a fingerprint of the modified device was taken again.

This incident was concluded so successfully that two mutually beneficial results were obtained: The problems of EMI in the clinical environment were clearly and graphically demonstrated within the institution, and the hospital obtained funding for the purchase of modern signal analysis equipment.

An Unusual Source

Another "ghost hunt" occurred at one of the biomedical engineering departments' client hospitals. The wireless medical telemetry there began intermittently displaying error

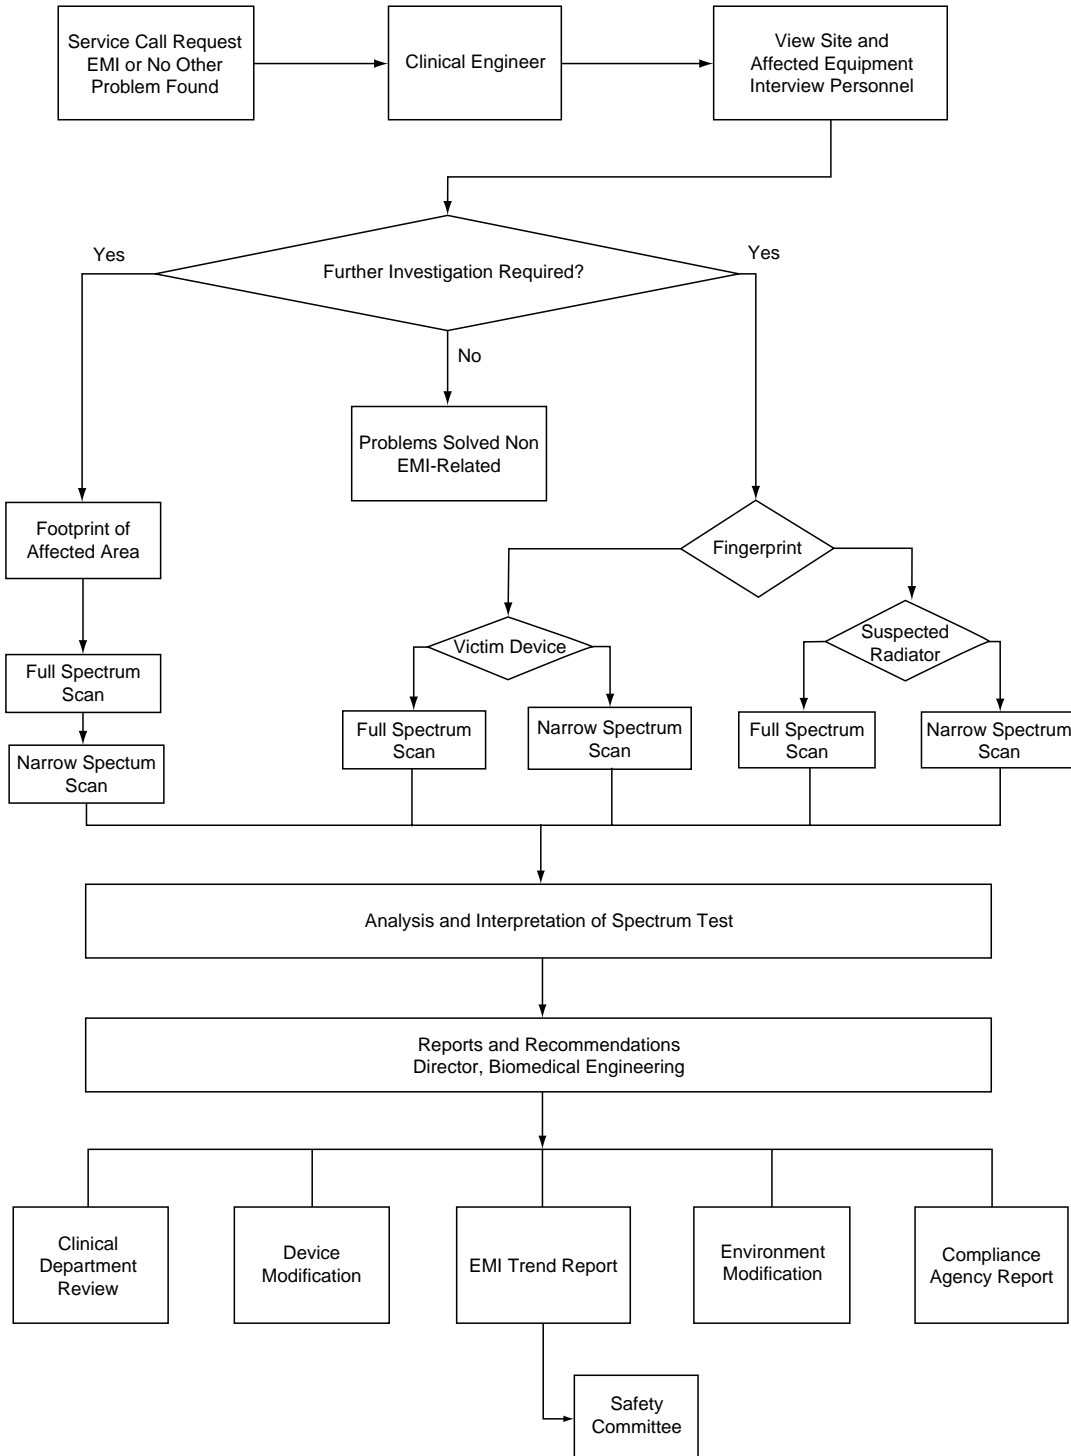

Figure 63-2 EMI problem resolution flowchart.

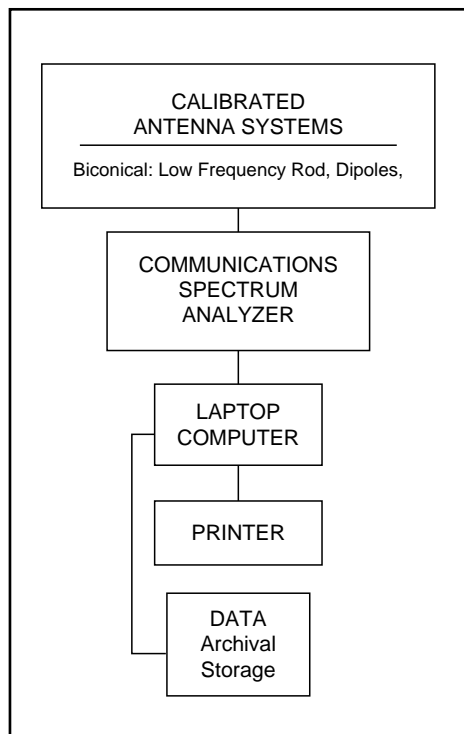

Figure 63-3 Typical equipment configuration for fingerprinting and footprinting.

codes (i.e., loss of data). Staff members were carefully questioned. The times when the interference occurred were established. Further probing revealed that a recently upgraded fire alarm system was undergoing acceptance tests during the periods of interference. As this would be an unusual source of interference, cooperation was sought from plant engineering personnel and the representatives of the fire detection company. Questions posed to the fire detection engineers yielded no prior indications of interference. A spectrum analyzer and broadband antenna system were set up at the site. The spectrum analyzer showed the presence of a recurrent but not time repetitive pulse, indicating that the interference source was radiating a quasi-random pulse.

Working with the fire alarm and plant engineering personnel, circuits controlling the various alarm devices were isolated and shut down individually. When no results were obtained on the affected floor, the same shut-down procedure was implemented on the floor below. When the enunciators—the audio-visual (A/V) units that proved audible and visual warnings of a fire—were shut down one floor below the affected area, the pulse and the interference effects disappeared. The floor below the affected area was a mechanical plant floor, and so the fire alarm company had installed high-powered A/V units. These A/V units used strobe lights. On discharge, these devices emitted a fast-rising, short-duration pulse. The telemetry antennas were receiving these pulses. However, the preamplifiers in the antennas and in the receivers themselves were not saturating or being desensitized by these pulses because the pulse was of such short duration. The pulses passed right through the RF portions of the telemetry system and corrupted data bytes. Open junction boxes with excess wiring hanging in circular loops contributed to the radiation of the pulses. Properly closing the junction boxes and replacing the strobe lights with lower intensity devices within fire code guidelines resolved the situation.

Risk Prevention

The following is an example of how the application of footprinting and fingerprinting may have prevented an EMI incident. The diagnostic imaging department bought new telemetry equipment. Footprinting revealed that the level of incidental emissions in that department was approximately sixty-seven microvolts. Fingerprinting a representative telemetry transmitter showed that the transmitted energy level at the standard one-meter distance was 12 microvolts above the background level.

The defined risk was that there was not sufficient signal-to-noise ratio to preclude intolerably long periods of loss of useable signal throughput. Testing the telemetry transmitter (fingerprinting) is done under controlled conditions at a fixed distance that can not be maintained under real world conditions. A patient wearing a telemetry transmitter can not be expected to maintain a 1-meter distance from the receiving antennas. As the distance between a patient and the receiving antennas increases, the received signal degrades because of the various topographical conditions and the inverse square law. As the signal degrades, the level of acceptable data degrades accordingly. If the degradation is significant, there is a chance that the telemetry system will not be able to recognize the emergency if a patient is in cardiac distress.

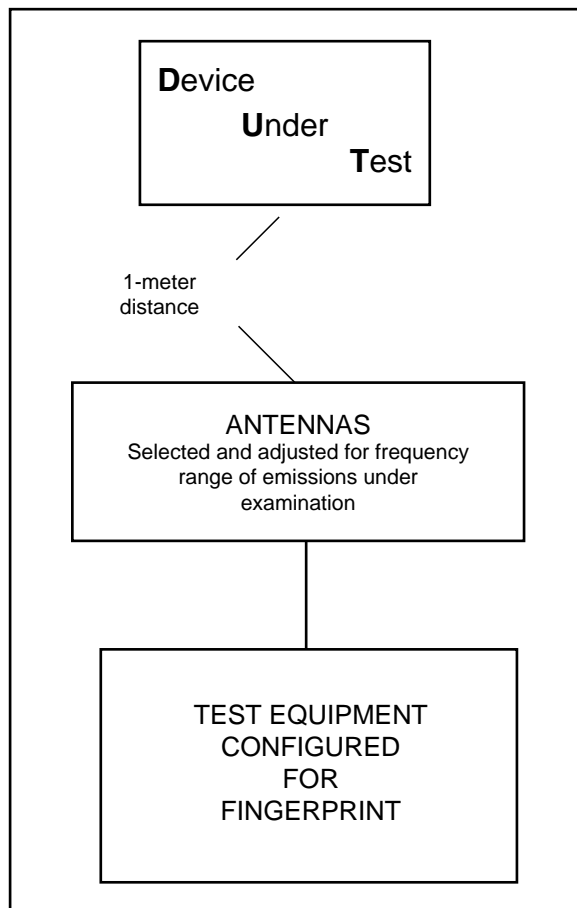

Figure 63-4 Fingerprinting.

Interference of Another Type

But not all ghosts are due to radiated or conducted electromagnetic fields. For example, a report was received of intermittent interference to an EMG device in the physical therapy department of the hospital. The department felt that the culprit was the MRI system located directly above the area containing the victim device. During footprinting, measurements entailing more than the normal broad spectrum procedures were indicated. In this application, the fingerprinting equipment was set up to measuring any radiated electromagnetic fields at the resonant frequency of the MRI that might leak from the shielded room environment that contains the MRI system. During a period of several hours, no leakage was detected. A broader spectrum scan showed that this department was in a remarkably quiet location with respect to radio frequency energy.

Further interviews with the doctors and staff led the clinical engineer to perform a somewhat unorthodox series of tests. The filtration on the EMG was broadened and the leads laid out, unterminated, on the couch on which patients were placed. During this procedure the clinical engineer observed that, when pressure was applied to the couch cushion, the baseline of the EMG machine would vary synchronously. Several additional adjustments to the sensitivity (gain) of the device and the time base were made. It then appeared that any motion in the immediate vicinity of the device would cause this baseline shift. Based on the results of these tests and of an investigation that determined the material composition of the environment (vinyl cushions on the couch and highly waxed vinyl floor), the engineer concluded that the cause of the interference with the device was electrostatic, not electromagnetic. Furthermore, the intermittent appearance of the problem was attributed to the fact that hydrotherapeutic baths were located two doors away from the EMG room. Their intermittent operation would raise the humidity sufficiently to reduce the potential for the generation of intense electrostatic charges. This was a decidedly different ghost hunt.

Interference Not Caused by EMI

One of the recent trends related to electromagnetic interference is that of a manufacturer's technical problems being attributed to EMI. Although EMI may play a significant role in the performance degradation in certain clinical devices, it is not always the cause. One example involved radiological equipment. X-ray films from one of the radiology labs displayed an artifact described by the radiologists as "chicken scratches." This artifact was present primarily during a Temporomandibular Joint (TMJ) procedure. This artifact was initially attributed to either conducted or radiated electromagnetic interference, specifically conducted EMI from the power lines. An outside consultant measured

radiation from the power lines, but there was insufficient indication that the artifact was due to the power system. After several months, the biomedical engineering department was called in for consultation.

Initial investigation, including timing the artifacts as they appeared on the film, indicated some degree of synchronicity (timing repeatability). This implied that the interference was time-locked (synchronized) within the radiology system. Due to the characteristics of the interference, such as the timing (frequency) of the interference in relationship to the scan rate, a probe was designed, constructed, and tuned to resonate within the frequency range of the suspected interfering signal. A thorough investigation of the areas surrounding the radiology suite included probing of the three-phase electrical service panels that provided the distribution of power to the suite. No high levels of radiated electromagnetic energy were encountered within the frequency of interest. The investigation was then conducted within the radiology suite. Despite intensive probing of all devices within the suite, including video monitors, computers, and control systems, and examination of the system involved in the TMJ procedure during which these artifacts most often appeared, the source could not be attributed to electromagnetic interference.

A detailed report was filed with the radiology department. The manufacturer's representative was called in. Based on the inconclusive findings, a greater in-depth analysis of the problem was conducted by the representative, the clinical engineer, and technicians from the biomedical engineering department radiology group. During the analysis, the investigators discovered a disconnected bonding strap within the camera head. Reconnecting this strap improved the performance of the system and reduced the artifact.

This incident further illustrates the benefits of cooperation to resolve interference issues, irrespective of the sources of interference. It also demonstrates the effectiveness of a proactive, competent, and supported electromagnetic interference program in the clinical environment. Placing blame rarely mitigates risks.

Variability: A Demonstration of the Problem

Variability in the repeat cause and effect (culprit/victim) device relationship poses a problem when instituting proactive programs designed to reduce the risks attributable to EMI with the support of management.

In 1996, at the request of NHK (Japan Educational Television), the television services group of the biomedical engineering department at the Texas Children's Hospital in Houston was asked to contribute a segment to an educational program about electromagnetic interference issues in the hospital environment. The hospital administrators decided that a demonstration of EMI using actual medical equipment would meet the program's objectives of demonstrating the variability of effects of a common source radiator on identical clinical devices.

Two of the same model of hemodialysis machines from the same manufacturer were used in the demonstration. Under the supervision of the clinical engineer, the machines were prepared in such a way that accessories, calibrations, wiring positions within the devices, and location within the demonstration area were as identical as possible.

An intentional radiating source was placed in transmit mode at a distance of 1 meter from the clinical devices. The source was a walkie-talkie commonly encountered in the environment (151.625 MHz frequency band, measured power output of 4 watts at the transmitter, antenna efficiency of approximately 40%, frequency modulation at 5-KHz deviation). The results illustrated the issue of variable susceptibility. One device failed repeatedly in a noncatastrophic condition, while the other device, located nearby, was unaffected.

Demonstrations such as this, performed on demand, tend to support the many anecdotal EMI-related reports that our department receives daily from other institutions. Regrettably, many EMI incidents go unreported due to a lack of specific programs to address them.

The varied nature of EMI-related equipment malfunctions and the associated risks mandate a proactive program of EMI identification and methodology for risk reduction. An effective program relies on the cooperation of all parties potentially affected by EMI: medical staff, plant engineering, information services, biomedical engineering, and device manufacturers. Due to the highly diversified knowledge and experience required to coordinate detection and mitigation of EMI, the clinical engineering department and its personnel experienced in RF must take responsibility.

An operational protocol must be developed to address EMI issues. (See Figure 63-5.) This provides a defined structure to process requests for EMI investigations and a structure for processing and reporting the results of the investigations.

Programs and Procedures

Testing for electromagnetic compatibility (EMC) in the clinical environment introduces a host of complex conditions not normally encountered in laboratory situations. In the clinical environment, various RF sources of EMI may be present anywhere. Isolating and analyzing the impact from the sources of interference involves a multidisciplinary approach based on training in and knowledge of the following:

- Operation of medical devices and their susceptibility to EMI
- RF propagation modalities and interaction theory
- Spectrum-analysis systems and technique (preferably with signature analysis capabilities) and calibrated antennas
- Established methodology of investigating suspected EMI problems, which includes testing protocols and standards

Both standard test procedures adapted for the clinical environment and personnel trained in RF behavior increase the odds of proactively controlling EMI in the clinical environment, thus providing a safer and more effective patient care environment. The methods employed in the following procedures are variations of the OATS (Open Antenna Test Site) technique

(ECRI, 1992; ECRI, 1988), a standard for open site testing (Southwick, 1992; Bennett, 1993; ANSI, 1991) and ANSI C63.4-1991 (ANSI, 1991) and ANSI C63.18-1997.

The selection of the spectrum analyzer and the options installed in it were influenced by several factors. A spectrum analyzer of the communications system test type was deemed desirable because there is no better way to characterize devices that emit RF—intentional or incidental—and the environment in which those devices operate. Broadband devices indicate relative RF activity but do not indicate the operating frequencies or modulation types. Both characteristics, independently and together, affect the susceptibility of clinical devices. Table 63.1 shows the test equipment used for EMI testing by Texas Children's Hospital's Biomedical Engineering Department.

A digitally based communications analyzer was needed to archive the results of the EMI tests; both fingerprints and footprints. The flexibility of performance requirements of the device was important, and as a cost-saving benefit, Texas Children's Hospital also uses it to maintain of the hospital radio communications systems.

Since no two modified OATS environments are identical, no two results obtained under the same testing parameters will be identical. Many factors affect the detailed test results, including complex absorption and reflection variables that are totally site-dependant.

Footprinting

At Texas Children's Hospital, the EMI testing program has evolved from years of experience and analysis. This program is not static. Sources of EMI and susceptibility characteristics of devices are in constant change. As new threats arise, the plan is periodically reviewed and modified to contend with them. Further modifications to the plan and procedures are based on a continuous review of wireless industry trends. They represent a proactive response to perceived future threats. At present the program consists of the procedural plan outlined above and three series of tests: (1) area characterization, footprinting (Figure 63-3), (2) device characterization, fingerprinting (Figure 63-4), and *ad hoc* susceptibility testing according to IEEE guidelines (Knudson and Bulkeley, 1994).

Footprinting an area means performing a series of spectrum/amplitude scans for electromagnetic radiation in a defined or designated area. Footprinting is an ongoing technique that defines electromagnetic radiation in a clinical facility or facilities in a multibuilding campus. Footprinting is also done upon request from a department experiencing performance degradation of clinical, diagnostic, or therapeutic devices when EMI is the suspect. The procedure involves a series of 20-MHz-wide spectrum sweeps, beginning at 2 MHz and ending at 1 GHz with antenna(s) in the horizontal plane. This procedure is repeated with the antenna(s) vertically polarized. Tunable standard antennas are adjusted for the correct resonant length for the center of each 20-MHz window.

The footprinting procedures yield two results: An overview of the radiated electromagnetic fields present at a specified location in the environment and the amplitudes and types of emission of those fields. Several incident investigations have been successful using this information. In cases where EMI has been site-originated, the source has been removed and the problem has been corrected. In some cases, the affected device required maintenance to correct the problem. An added value of footprinting is that the data obtained during the process meets the basic requirements for a site search similar to the OATS procedure for fingerprinting individual devices. The results of the footprinting scans are transferred to a storage medium and filed. They form a comparison database that is used to evaluate new devices before introducing them into a specified area.

Fingerprinting

The process of fingerprinting a device has several steps. Again, the spectrum analyzer and calibrated antenna system are the primary tools used to analyze the device under test (DUT) (see Figure 63-4). To minimize the loss of information from the DUT due to masking by other sources of electromagnetic radiation, areas within the clinical physical plant should be tested using the footprinting procedure until a relatively quiet area is found.

For the fingerprinting procedure, as in the footprinting procedures, the standard antenna should be located as far as possible from any conductive material. The standard antenna should be located at a height equal to the center of the DUT. Due to constantly changing EM fields and frequencies, they execute the footprinting procedure in the selected area immediately prior to fingerprinting the DUT. Once the data from the latest footprint has been stored, place the DUT on a nonmetallic stand located as far as possible from any conductive material. The standard antenna(s) is then mounted on a tripod and, in a horizontally polarized mode, placed 1 meter from the front of the DUT. As in the footprint procedure, a series of 20-MHz-wide spectrum sweeps are performed and the results are recorded. This procedure is repeated with the antenna(s) vertically polarized. When using tunable standard antennas, adjust them to the correct resonant length for the center of each 20-MHz window. Upon review of the data collected, any emissions attributable to the DUT should be rescanned. To increase detail in the frequency range in which the emissions were observed, the spectrum analyzer window is narrowed to a 200-KHz/division or smaller, (e.g., 5 KHz/division) sweep width.

Fingerprinting tests are conducted for two reasons. First, compliance with hospital policy on acceptance testing requires that representative samples of all devices be tested prior to entering the clinical environment for the first time. Second, both theory and experience have demonstrated the need for device testing. A device that radiates unintentionally can victimize other devices. It may also be susceptible to victimization by ingress at their egress frequencies and modulation parameters. Those devices already in the environment are fingerprinted if there is reason to believe that they have the potential to be an EMI victim or a culprit.

The procedure used to initiate and track an EMI investigation is shown in Figure 63-2. Members of the clinical staff are instructed to call the biomedical engineering department and television services group in any case of a device malfunction not attributable to a routine failure. In cases of a new device entering the clinical environment for the first time or a new application for an existing device, a request to test the device for compatibility is generated. This call is referred to the clinical engineer responsible for EMI investigations. When an incident might be attributable to EMI, the engineer visits the site as a part

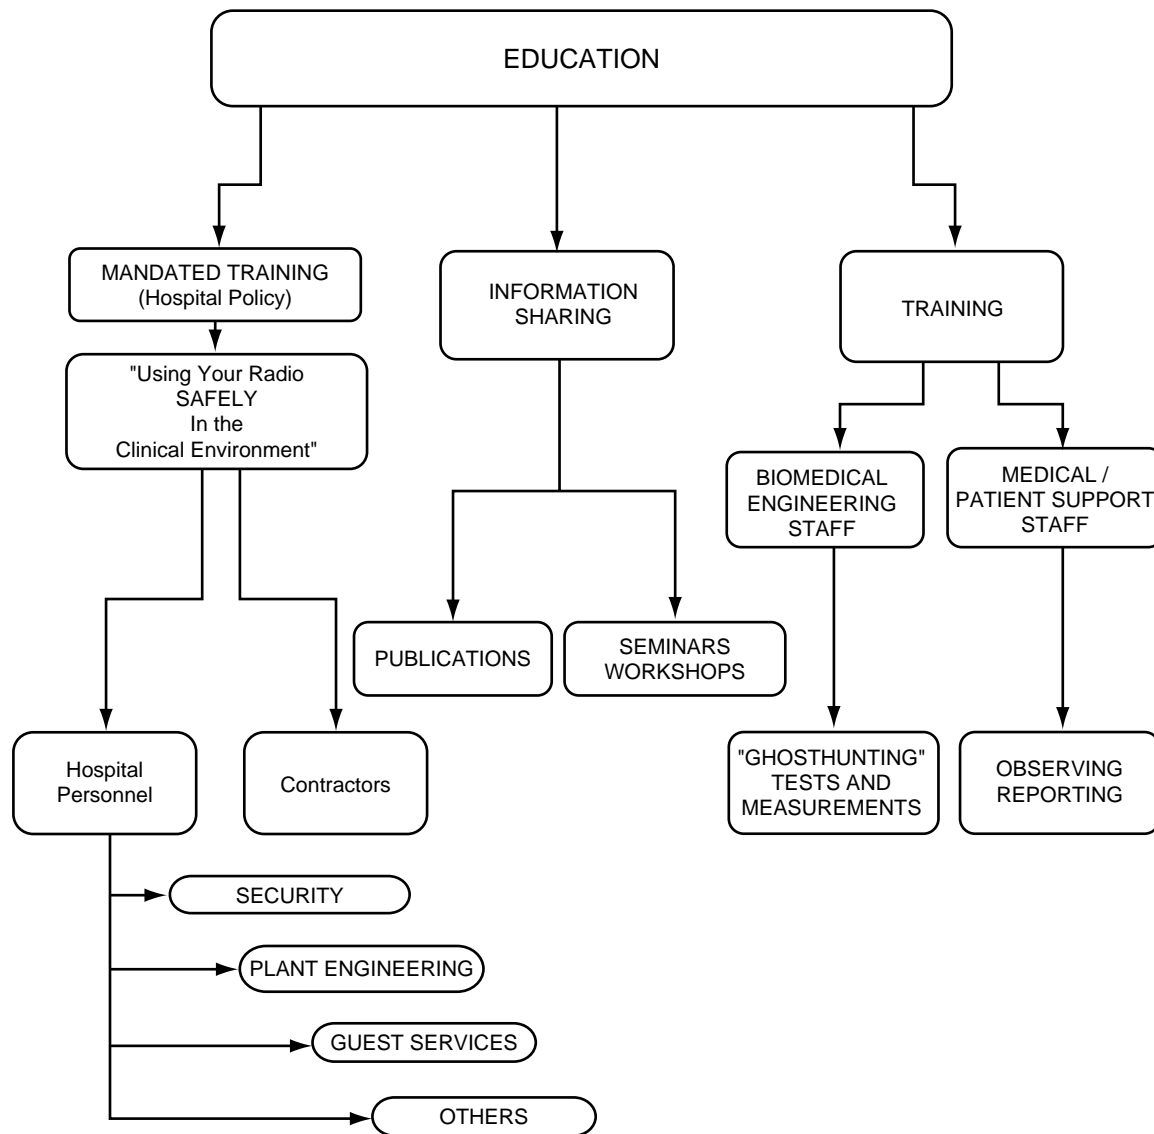

Figure 63-5 Flow diagram of hospital educational program in electromagnetic compatibility and interference relating to medical device technologies.

of the initial investigation. The possible victim device is viewed and tested to determine whether it might have been, or is being, affected by EMI. Interviews with the personnel responsible for the area and the operation of the device(s) must be conducted. Based on the results of this preliminary investigation, a decision is reached as to the desirability or feasibility of further investigation.

The decision to continue the investigation is based on several factors: Is there a high probability of operator error? Is this a very rare occurrence? Is this either a very old device that might be reaching the end of its reliable life cycle or a new device experiencing infant mortality. As part of the preliminary investigation process, maintenance histories of the device are reviewed. Another component involves the review of equipment added to the environment that might have increased the overall RF hostility in the area enough to cause interference. Footprinting records of the area are reviewed as are fingerprints of the victim device(s).

The mode of device failure (table 63-2) is an important part of the evaluation. Is the victim device alarming? Is it operating erratically? Is it changing its operational parameters either temporarily or permanently? Is it shutting down? Is there a latching change that created the alarm? The answers to these questions can all point to the criminal device or devices. If the failure mode can be duplicated and if the failure appears to have been caused by an intentional or incidental radiator, the culprit device can usually be identified. If it is within the clinical environment, it is silenced or removed. Many times, no further investigation is required. An incident report is generated and filed. A copy is provided to the department initiating the service request. A copy, if deemed necessary, is given to the appropriate reporting agency, such as the Food and Drug Administration Center for Devices and Radiological Health (FDA, CDRH).

If a complete testing procedure is required and a recent footprint of the area exists, a new set is acquired and compared to the older set. Changes in the area environment are noted and analyzed. This is also compared with any existing fingerprints of the victim device. If no fingerprints exist for a representative victim device, or when a device shows signs that its ability to resist ingress may be compromised, it will be fingerprinted. After

a cursory footprint of the quiet area, to ensure that no significant changes have occurred in that environment, the victim device, if practical (size and weight can affect the test location), can be moved to this area for fingerprinting.

Generally, the fingerprinting procedure depends on the operating characteristics of the device. For example, intentional radiators are tested for emissions at their operating frequencies, modulations, and at second and third harmonic frequencies. Unintentional radiators (i.e., microprocessor controlled devices) are tested from 1/4 clock frequency to 300 MHz. There are exceptions to this guideline, such as when relatively strong emissions continue to the 300 MHz point. In these cases, readings are continued to 1 GHz. The new digital cellular telephones (GSM) are now in service. Third Generation (3G) wireless communications devices should be in service in the near future. The Biomedical Engineering Department has already received reports of interference to clinical devices by digital telephones.

As both the fingerprint and footprint tests proceed, the records presented by the spectrum analyzer are reviewed. Any RF emissions exceeding a predetermined value are noted, especially frequencies not easily correlated to known sources of intentional radiation. The window of observation is then narrowed to obtain a greater resolution, or magnification, of the emission of interest. This typically identifies the type of modulation of the intentional radiator. After the series of footprinting and fingerprinting tests have been completed, both the clinical engineer and the technician performing the tests analyze the results and generate reports and recommendations. These are discussed with the Director of Biomedical Engineering and possible resolutions of the problem are analyzed and reviewed.

There is not always an ideal solution to an interference problem. Many factors may contribute to device victimization, some of which are not easily or practically resolved. For example, if a recently added high-power paging transmitter were installed on an adjacent building, the additional energy radiated could affect devices that exhibited no previous EMI-related reactions. Historically, if the licensed transmitter is installed on a building over which the institution has no control, it will be difficult to remove. Such

transmitters are licensed by the Federal Communications Commission and the medical device has no statutory protection; a one-way street (see Chapter 103).

Modifications to the environment are recommended if they are practical. These might include screening an area or relocating a device within an area. If modification of a medical device appears to be the only solution to the problem, then the manufacturer of the device is advised of the problem. The biomedical engineering department can and does advise the manufacturer. Ad hoc modifications of medical devices to mitigate susceptibility or egress are improper and should not be attempted. Performing such modifications would, in most cases, be a violation of FDA regulations and would increase the institution's risk for liability.

Summary

Despite gains in spectrum protection for some categories of patient monitoring devices through the development of standards, the overall electromagnetic environment is becoming increasingly hostile to the safe operation of clinical devices (see Chapter 103). The establishment and maintenance of a safe environment for the operation of clinical devices requires a multidisciplinary approach. There must be a program of education involving technical, clinical, maintenance, and management personnel and staff. A clinical engineer experienced in RF and EMI, as well as in appropriate test and measurement equipment, must be available.

A proactive testing and evaluation program that includes ongoing measurements of plant and incoming devices must be established. Maintained devices—especially those that have demonstrated a potential for electromagnetic wave to be spot-tested periodically, using the fingerprint method.

This chapter has presented the need for a proactive EMI management program designed to limit the destructive effects of EMI on clinical devices. Some of the previously mentioned causes of EMI and methods used to test both the environment and the devices within it are based on experiences at Texas Children's Hospital.

Accident Investigation

Joseph F. Dyro

President, Biomedical Resource Group
Setauket, NY

The increased dependence of caregivers on medical devices, the increased complexity of medical device design and capabilities, the increased pressure on medical staff to operate efficiently and cost-effectively, the decrease in training opportunities, and human error contribute substantially to medical device-related accidents in the health care setting.

Accidents involving medical devices have occurred and will continue to occur for many reasons, including device design, human error, and lack of training. Accident investigation addresses several concerns: improved patient safety, elimination and reduction of risk, prevention of recurrence, compliance with regulatory imperatives, and discovery of facts that support the litigation that often follows a serious injury.

An accident response system with policies and procedures, resources to implement them, and administrative support should be in place in all institutions so that staff members and departments are aware of their respective responsibilities if an accident occurs. The clinical engineer (CE) must take a leadership role in any accident response system. This chapter introduces the clinical engineer to accident investigation and recommends that the CE develop the skills necessary to perform investigations either as an independent consultant or as an employee of the hospital or independent service provider. This chapter describes the methodology and tools that enable the CE to put accident investigation into practice.

Forensic clinical engineering examination and analysis, either as medical device safety officer or as independent forensic engineer, requires skills in accident investigation. Accident investigation yields best results when the hospital administrators and staff cooperate with a sound understanding of policies and procedures pertaining to accidents. Techniques are described for addressing the issues of evidence, documentation, reconstruction, investigation tools, interviews, root cause analysis, reports, and recommendations.

This chapter also provides methods for the CE who investigates accidents involving the use of medical devices. A systems analysis technique guides the investigator through five factors that often contribute to accidents: The facility, the operator, the patient, the device, and the environment. Several case studies are presented in which the methods described enabled the identification of failure mechanisms contributing to injury and death. The methods are applicable to a wide range of medical devices used in the hospital and in the home setting. The chapter also offers an accident investigation checklist to

aid the clinical engineer in acquiring and documenting relevant details important in forensic examination. Education in accident investigation and available resources are also presented.

While this chapter focuses on accidents, it is equally applicable to the critical incident technique. The investigative techniques described apply to the identification of preventable incidents that could have led, or did lead, to an undesirable outcome. The occurrence rate of preventable incidents may be reduced through the investigation of "near misses" and "no-harm events" as well as adverse events (Cooper, 1978).

Rationale for Medical Device Accident Investigation

Accident investigation is done for many reasons, including public pressure to reduce medical errors and improve the quality of care, regulatory imperatives, and legal and ethical considerations. A principle objective of accident investigation is to discover the cause of the accident (Shepherd, 2000). Once identified, the cause can be addressed, eliminated, or controlled, with a reduced likelihood of recurrence. Improvement in quality of care follows a comprehensive accident investigation that reveals the root-cause and yields recommendations for improvements in the health enterprise, personnel, maintainers, and medical device manufacturers and distributors (Driscoll, 2003; Patail and Bruley, 2002; Bery and Krizek, 2000; ECRI, 2001; JCAHO, 2000).

Patient Safety Movement

The public demands an appropriate response from health care providers in the wake of reports of deaths and serious injuries that occur in hospitals (Kohn et al., 2000). Organizations of health care professionals are unified in their support of patient safety initiatives (ACCE, 2001; JCAHO, 2001; Shojania et al., 2001; Shepherd, 1999; Dyro, 2000). The Institute of Medicine (IOM, 2001) in its report, "Crossing the Quality Chasm: A New Health System for the 21st Century," calls for a health care delivery system that is safe, effective, patient-centered, timely, efficient and equitable. Patient safety

can be enhanced by improving the ability to learn from mistakes. Skillful investigation of incidents and responsible sharing of data will help in the identification of root causes of error (ACCE, 2001). Accident investigation alone will not address the issue of risk due to medical technology. Investigation will, however, provide valuable insight into the root causes of a specific injury or a class of injuries that, if addressed, will minimize the odds of recurrence.

Effective risk management (see Chapter 56), a vigorous patient safety program (see Chapter 58), and a strong clinical engineering presence are essential in enhancing patient safety (Dyro, 1988). Attention to accident investigation will heighten the hospital staff awareness of the existence of an active patient safety and risk reduction program. Shifting the emphasis from blaming the individual to seeking the root cause will encourage disclosure of accidents that otherwise might have gone unreported for fear of blame, retribution, and punishment (Shepherd, 2000a).

Investigation techniques that use the preferred systems approach (Shepherd, 1993) will increase the hospital employee's awareness of the elements of the "system" and of element interactions, such as device-device interference, that lead to inappropriate patient care. Hospital employees will recognize that accident investigation by the clinical engineer is only one of the many facets of technology management and that they can be active participants in the safety team by being alert to device malfunctions, such as unusual odors, unexpected or erratic functioning, or electrical sparks.

Regulatory Imperative

The United States Food and Drug Administration (FDA) is charged under the 1976 amendments to the Food, Drug, and Cosmetics Act to regulate medical devices for the public good. Since then, many initiatives that place responsibility for post-market surveillance on manufacturers, distributors, and health care providers (hospitals and individuals) have been launched. The Safe Medical Devices Act (SMDA) requires that a hospital report any incident in which the manufacturer's medical device may have contributed to the injury to the manufacturer within 10 business days. If the manufacturer is unknown, the occurrence must be reported to the FDA. The FDA follows post-market surveillance with policies and procedures to gather information to fulfill its mandate to protect the public. (For more on the FDA, see Chapter 126.) The Joint Commission on Accreditation of Healthcare Organizations (JCAHO) requires that hospitals have a mechanism to analyze and reduce through corrective action sentinel events, i.e., an unexpected occurrence involving death or serious physical or psychological injury, or the risk thereof (JCAHO, 2001). OSHA must be alerted when an employee's health has been compromised by an injury in the workplace. The state health department, and local, regional, and national authorities have reporting requirements for accidents that result in injuries. In the event of any workplace injury, it is in the hospital's best interest to launch its own investigation quickly.

Litigation

A death or serious injury that occurs unexpectedly in a hospital may lead to a lawsuit. A medical device-related death or injury may result in the injured party, the plaintiff, suing several entities and individuals including the hospital, doctors, nurses, technicians, support staff, the device maintainer, the distributor and the manufacturer of the device. The hospital that immediately conducts a thorough investigation can better assemble facts and evidence that could shift liability from the hospital and its personnel to another party, such as the manufacturer of a defective device.

Ethics

The American College of Clinical Engineering states that the first tenet of the ACCE Code of Ethics calls upon clinical engineers "to strive to prevent a person from being placed at risk of injury due to dangerous or defective devices or procedures (ACCE, 2001)."

Role of the Clinical Engineer as Investigator

The CE is the logical choice as the investigator of medical device-related accidents (see Chapter 55, Patient Safety and the Clinical Engineer, and Chapter 13, The Clinical Engineer as Investigator and Expert Witness). By education, training, and experience, the CE is the one hospital employee who has the greatest knowledge of the principles of operation of medical devices. The American College of Clinical Engineering Health Technology Foundation (AHTF), acknowledging that clinical engineers are engaged in accident investigation, has drafted guidelines for incident investigations (AHTF, 2003).

The clinical engineer is a logical choice to serve as the medical device safety officer in a hospital. The CE is skilled in safety awareness education and training, accident investigation and analysis of the causes of accidents, and documenting and reporting findings. The CE can serve as the coordinator of investigations. Hospital CEs should recuse themselves from the role of primary investigator when the device involved in the accident is one serviced, maintained, and repaired by the clinical engineering department. In such cases, the services of an independent CE should be retained. An independent clinical engineer may work in another hospital, as an independent consultant (see Chapter 13), or working in an organization that specializes in medical device testing and evaluation.

Response to Accident

An accident should be responded to immediately. Resources must be available on a 24-hour, 7-days-per-week basis. Policies and procedures must be in place to guide the accident response and the subsequent investigation. Adequate training must prepare staff members to react appropriately in an emergency situation. An accident in one department ultimately involves many parts of the hospital, such as administration, risk management, legal affairs, clinical engineers, staff development, safety officer, medical staff, and nursing department. All must know the appropriate documentation required by hospital policy and by local, state and federal regulatory bodies. It may be necessary to notify outside authorities and organizations such as the local fire department, environmental protection agency, OSHA, the FDA, the device manufacturer or distributor. The hospital must be prepared to notify and interact with these entities.

General Guidelines

The first response to an accident is to protect the injured party or parties from further harm, e.g., removing a patient away from a fire. The injury should be assessed and treated by the medical team immediately. Attention should then be directed to controlling the source of the danger, for example, extinguishing the fire. Clinical engineering should come to the scene. It may be necessary to call for assistance or to activate alarms at this point, such as calls to maintenance if the problem involves the facility's utilities or physical plant, calls to the fire department in case of fire, calls to the infection control officer if the accident involved the release of an infectious agent. Once the source of danger is contained, the facility should be inspected for changes that could adversely affect other patients, such as loss of power or smoke in the air handling system. The environment should be checked so as to ensure that other devices were not adversely affected by the accident. For example, if a power surge caused a device to injure a patient, that surge may have adversely affected the operating characteristics of devices powered by the same circuit.

Next, an accurate description of the occurrence should be entered into the medical record and an incident report should be completed. Notify other hospital personnel—risk management, public affairs, and chief operating officer—of the hospital policy and procedures.

Policies and Procedures

Policies and procedures must be in place to guide the accident response and subsequent investigation.

Administration, legal affairs, risk management policies and procedures should be crafted for the following:

- Policy: Incident Reports
- Procedure: Preparation and Processing of Incident Reports
- Policy: Safe Medical Device Act Reporting
- Procedure: Preparation and Processing of Incident Reports Affected by Safe Medical Devices Act

The clinical engineering department should have the following:

- Policy: Incident Investigations
- Standard Operating Procedure: Incident Investigation

This procedure should incorporate the details of incident investigation described in this chapter, e.g., preservation of evidence, data collection, photography, interviewing witnesses, and report preparations.

A Sample Clinical Engineering Policy Regarding Incident Investigations is shown below:

Clinical Engineering Policy Regarding Incident Investigations

Clinical engineering has the responsibility to investigate and report on all incidents at John Endall Hospital that involve medical devices. This responsibility is detailed in Management Manual Policy 008. The purpose of these investigations is to discover the facts surrounding an incident, analyze them, and propose recommendations that will lessen the possibility of recurrence. Additionally, Clinical Engineering must report these incidents to the Hospital's Equipment Quality Performance Committee, to device manufacturers, and the FDA according to the regulations imposed by the Safe Medical Device Act of 1990.

Individuals contacted by clinical engineering in the course of an incident investigation should be as candid as possible to facilitate fact-finding. The purpose of these investigations is to improve the quality of patient care, not to fix blame. Except as necessary for reporting, information contributed will be kept confidential.

Clinical engineering strives to maintain objectivity in all its incident investigations. The actions of clinical engineering are subject to comment and recommendation, as are those of other departments and medical staff. In cases where maintaining objectivity is difficult, an outside party may conduct an investigation after legal affairs is consulted.

Clinical engineering's years of experience in investigating variances at John Endall Hospital have repeatedly shown individuals to be helpful and cooperative in supplying information and in working together to find solutions to problems. We look forward to continuing to serve you and our patients in this capacity.

John B. Booté
Director, Clinical Engineering

Team Approach: Medical Staff, Nursing, and Risk Management

Adequate training ensures that staff members are prepared to react appropriately in an emergency. An accident in one department ultimately involves many parts of the hospital organization such as administration, risk management, legal affairs, clinical engineers, staff development, safety officer, medical staff, and nursing department.

Clinical Engineering

Clinical engineers should respond immediately to the scene of an accident. Steps to be taken include the following:

- Preventing or minimizing further injury or damage to patients and staff
- Establishing a perimeter and cordon off with to minimize loss or alteration of evidence
- Checking for damage to ancillary devices and facilities
- Photographing, sketching, recording, and otherwise documenting the scene
- Obtaining first-hand witness accounts
- Beginning to establish a spatial frame of reference and a time line
- Preserving and sequester evidence
- Launching investigation

Documentation and Reporting

It may be necessary to notify outside authorities and organizations, such as the local fire department, Environmental Protection Agency (EPA), OSHA, FDA, the device manufacturer or distributor about an accident (FDA, 1996; Kessler, 1993). The clinical engineer must be prepared to not only notify but also interact with these entities. The hospital must be familiar with the appropriate documentation required by their own policy and by local, state and federal regulatory bodies.

Skills Requirements

Effective accident response and investigation requires that the clinical engineer possess technical expertise, knowledge of human factors (Guyton, 2002), and good communications skills. Expertise, knowledge, and communication skills are typically gained through formal and informal training and education, and from practical experience. ACCE in its clinical engineering certification process stresses that knowledge is required in human factors engineering, root cause analysis, and other fields of study related to patient safety (ACCE, 2001). ACCE Teleconference Series has featured conferences on these subjects (Shepherd, 1996; Dyro, 2000a; Patail and Bruley, 2002). A survey of clinical engineers established that accident investigation falls within the "body of knowledge" expected of a clinical engineer (Cohen, 2001).

Technical

A sound knowledge of clinical engineering in addition to good analytical ability and problem solving techniques is required for accident investigation. The knowledge must include the principles of operation of medical devices, the use of those devices to treat and diagnose patients, the fundamentals of physiology, and an understanding of the interaction of physical forces with the human body. For example, the effective accident investigator will understand the operation of a hypothermia machine and thermoregulation of the body. The CE will understand such phenomena as skin lesions and their causes, physiological response to and injury mechanisms of electricity, and mechanical forces and their effects upon the body.

Human Factors

The clinical engineer will find knowledge of human factors useful whether the CE is working in a hospital (see Chapter 83), as an independent forensic clinical engineer (Bogner, 1994), or as a design engineer (Gosbee, 1997; Gosbee et al., 2001). Cooper (1978; 1984) has shown that human factors analysis of adverse events and equipment design leads to a safer clinical environment.

A device involved in an accident could be found to be performing within its design specifications. However, the specifications may not have adequately taken into account the good human factors design and substituted a poor design feature, for example, a switch or a knob that could inadvertently be activated by a person brushing by causing a change in diagnostic measurement sensitivity or therapeutic energy output.

Communications

A medical device is one element of a system that includes the physical environment and its influences, plus the human elements—the patient and the device operator. Other hospital personnel or visitors may witness an accident, and the information they contribute can assist in determining the cause. Personal fact-finding interviews require good communication skills including socio-political awareness, clear speaking, and active listening skills. Documentation of the investigation and its findings, conclusions, and recommendations requires good writing skills.

Systems Approach

The systems approach to medical device accident and incident investigation (Shepherd, 1983) describes a system composed of five elements: Device, operator, facility, environment, and patient (see Chapter 59). For example, Figure 64-1 shows a diagram of a neonatal intensive care unit (NICU) containing the five elements. A neonate (the patient) is in an infant radiant warmer (the device) that is electrically powered from the wall receptacle (the facility). The operator (the nurse) prepares to connect the skin temperature sensor to the warmer's control panel. A nearby examination lamp and external influences of a bright sun and electromagnetic waves emitted by a local station (the environment) are shown. All five elements of the system can interact and cause an accident resulting in patient injury. The brief summary of the systems approach to accident investigation that follow stresses the importance of using the technique

All five elements of the system can interact and cause an accident resulting in patient injury. The brief summary of the systems approach to accident investigation that follow stresses the importance of using the technique

Medical Device

A medical device can contribute to patient injury as a result of defects and deficiencies that can be introduced into the device at a number of stages of its life cycle, including design, manufacture, transportation, inspection, maintenance, repair, post-market surveillance, and obsolescence.

Design

Device performance, accuracy, reproducibility, and safety require sound design and function of appropriate parts and components, the correct circuit diagrams and mechanical drawings, the optimal routing of wires, and adequate connectors. The theory of operation of the electrical and mechanical aspects must be based on sound principles, and the design must also consider mechanical shock and vibration, fluid ingress, electromagnetic interference, and electrostatic discharge (ECRI, 1974).

Sudden or unpredictable failure of a part or circuit is classified under this system sub-component. Device design should incorporate failure mode and effect analysis (FMEA) (Stamatis, 1995; Stalhandske et al., 2000; Willis, 1992). The effect of a sudden component failure on the operation of the device can be predicted. If the results endanger the patient, fail-safe design must be incorporated. Bruley (1994) described an incident in which a patient was crushed by a descending motorized radiotherapy gantry that did not stop in response to its normal operating control, its emergency stop, or its automatic limit switch. All three controls operated through the same electrical relay, which failed. FMEA would have predicted this failure mode and would have resulted in an alternate design in which relay failure would stop gantry movement.

Human factors design is that aspect of device design that operators, maintainers, and others use when working with the device (Christoffersen and Woods, 1999). A device may work as designed and may be safe and effective when used properly, but its design may confuse the operator or the maintainer such that it is utilized incorrectly or repaired improperly (Welch, 1998). Controls and indicators can be difficult to see. Examples include numbers on a control knob or display that are too small to be seen clearly or, if illuminated, are too dim in high ambient light conditions to be visible. Parts should not be able to fit into a device in ways other than those that are intended for proper device operation. For example, check valves that can be reversed in a breathing circuit have cut off air supply to patients. Attention to human factors design should be directed to evaluation and incoming inspection of medical devices (Hyman and Cram, 2002).

Connectors are device components with a long history of deficiency in human factors design. Proper markings, use of mechanical interlocks, keying, proper placement of connectors on the medical device, and color-coding are some of the means to minimize human error due to deficient human factors design. Figure 64-3 shows the use of a temperature sensor from another manufacturer's radiant warmer inserted into the connector of a warmer used to treat an infant. The radiant warmer overheated, causing brain damage to the infant.

The device-patient connection is often a weak link in the system. These connections involve such devices as tracheal tubes, needles for intravenous or intra-arterial lines, ECG electrodes, and temperature sensors. In a case study described below, a partially dislodged tracheal tube resting against the patient's neck, deprived air from entering the patient's lungs while preventing the low airway pressure alarm from activating because of the obstruction of the breathing circuit.

Figure 64-1 Systems approach to medical device accident investigation: The neonatal intensive care unit. Adapted from *A Systems Approach to Hospital Medical Device Safety* (Shepherd, 1983).

Figure 64-2 Cigarette butt packed with surgical gloves

Manufacture

The medical device can be rendered defective during the manufacturing process. For example, a package of surgical gloves could be contaminated if a cigarette butt discarded by an assembly line worker is packed in with them. (see Figure 64-2). In another example, a misassembled PEEP valve resulted in the blocking of the exhalation port resulting in barotrauma and death of a ventilator-dependent patient. The packaging error in the former example was relatively easy to detect and resulted in no harm; the misassemble PEEP valve in the latter example was not checked, and led to grave consequences. Both examples underscore the importance of inspection prior to use of any medical device. Such inspection can often be as simple as visualization.

Transportation

The transport of a device from one location to the next, (e.g., from manufacturing plant to hospital loading dock or from an equipment storage room to a patient care area,) may subject the device to shock, vibration, temperature, and humidity extremes that the device was not designed to tolerate. One in three monitors of 120 purchased by one hospital failed incoming inspection in the author's experience because in transport a particular circuit board dislodged from its connector. The mechanical design was inadequate; it did not contemplate the typical stresses placed upon the monitor during shipping and, hence, did not provide for adequate retention mechanisms. Devices particularly susceptible to damage in transportation include surgical lasers, heart-lung machines, dialysis units, and incubators.

Inspection

Defects may be introduced during manufacture, assembly, or transportation. However, any device that arrives at a hospital must be inspected before it is used for patient care. Failure to do so permits the use of defective devices to the detriment of the patient.

Figure 64-3 A skin temperature sensor is taped to the control unit. The wrong sensor was used, and the sensor was secured to the control unit with white tape.

Maintenance

Circuits and parts can fail as a result of use, aging, and the environment. Maintainers of medical devices can make mistakes that lead to adverse events and injury to patients (Shepherd, 1998). For example, the maintainer can introduce a device defect by replacing a part with an incorrect part or by incorrectly installing a modification or upgrade. The author investigated an adverse occurrence in which the input and output lines on an anesthesia machine manifold were reversed by a serviceman, resulting in an anesthetic overdose and brain damage to a 13-month-old infant. Further investigation showed that the designs of the input and output lines were faulty from a human factors perspective—they were easily reversible and did not have adequate markings to indicate the proper assembly. The author procured the modification kit from the manufacturer and with little difficulty was able to cross-connect the input and output lines to the manifold. The instructions for the modification were poorly written and poorly illustrated, adding to the confusion of the serviceman, who failed to check the results of his work with an anesthetic gas analyzer.

Recall and Modification Notices

Failure to address a recall or modification notice allows a defective device to continue in use at the patient's peril. On average, only 4% of devices subject to recalls are ever located and returned. Undoubtedly, this is due in large part to ineffective or non-existent recall and hazard alert systems in healthcare organizations.

User

The user is under increased pressure to perform work in as little time as possible to maximize profits for the enterprise. The burden of complicated technology is heavy and misuse or abuse is likely to occur (ECRI, 1993). Errors in the use of a medical device can stem from misuse, abuse, and inattention (Shepherd and Brown, 1992).

Misuse

Two examples of misuse are described as follows. Figure 64-3 shows the control unit of a radiant warmer with an incorrect temperature sensor attached. The wrong sensor was used and a nurse who noticed that the connector was loose in the jack secured the sensor to the control unit with white tape. Lethal hyperthermia resulted from this misuse. This error was in part attributable to the defective human factors design of the temperature sensor connector that enabled it to be plugged into the wrong jack. The neonatal intensive care unit (NICU) used warmers made by several manufacturers. The operator was unaware of the difference between the available connectors, and temperature sensor interchange was likely to occur. The nurse erred in attempting to remedy a situation by making a technical adjustment with the use of white tape (Kermit, 2000; Shepherd, 2000b; Shepherd and Dyro, 1982) rather than calling for clinical engineering service.

An infant suffered lesions to the groin area while cared for in an intensive care unit of a major children's hospital. The infant warmer's high temperature alarm activated frequently. When the alarm sounded, the heating stopped, and the reset button needed to be pressed to resume heating. The simple solution for the nurse was to tape over the reset button, which meant that the warmer operated in continuous heat mode (see Figure 64-4). Betadine that had pooled in the groin area, combined with the irradiance from the warmer, resulted in skin lesions. Investigation of the incident soon after its occurrence found that

Figure 64-4 The high temperature alarm and heater output reset button shows the residue of white adhesive tape remaining on the surface of the control panel around the reset button.

the radiant warmer was operating within its design specifications. Visual examination of the control panel revealed that the reset button had been taped down, as indicated by the residue of white tape left on the panel around the button.

Abuse

Abuse is typically unintentional, but may be intentional. For example, a nurse, hurriedly moving an incubator from an equipment storage room to the NICU, crashes the incubator into a wall or doorframe damaging controls or internal components. Figure 64-11 below describes this kind of device abuse.

Inattention

Long hours without sleep have adverse effects on the level of alertness of nurses and doctors. Sleep deprivation, ignorance, and distraction are factors in inattention to both the patient and the device. Studies have shown that accidents are most likely to occur on the late night to early morning, a.k.a. the graveyard shift (Abramson et al., 1980). Undoubtedly all these factors combined to result in the self-defibrillation incident that occurred in one hospital's emergency department (Iverson and Barsan, 1979).

Facility

The same factors that influence the performance of a device influence the adequacy of the facility to provide the necessary services, e.g., utilities.

Human Factors Design

The location of a wall receptacle in a location that results in the line cord running along the floor may result in the nurse tripping or the disconnecting the cord from the receptacle, or the cord being damaged by a wheel running over it (see Figure 64-1).

Part/Systems Design

The design of the facility includes such factors as the location of a window (see Figure 64-1) or the location of an electrical receptacle. See Chapter 95 for a case study in which a patient received a near-fatal electrical current because a line cord was routed in a way in which it could be damaged.

Deterioration

Facilities must be maintained and will deteriorate if they are not. The wall unit shown in Figure 64-1 contains medical gas outlets and suction in addition to electrical outlets. Allowing these utilities to deteriorate could adversely affect patient care. For example, the continual insertion and withdrawal of plugs into and from receptacles will eventually degrade the receptacle, resulting in poor electrical contact. Gas and suction outlets can leak over time, affecting pressures and flows. A leaking oxygen outlet is particularly dangerous as it could result in an oxygen-enriched atmosphere that, with fuel and an ignition source, could result in an intense fire.

Maintainer

The maintainer could cause a hazardous situation by, for example, replacing a defective receptacle with the wrong receptacle, e.g., replacing a regular power receptacle with a red one. If power subsequently fails, a critical life-support device such as a ventilator may fail to operate if it was connected to what a nurse thought was an emergency power outlet, but was instead a regular outlet.

Environment

The environment can be separated into two categories: The internal environment and the external environment.

External

In Figure 64-1, the examination lamp illuminates the internal environment. The lamp's output, while illuminating the neonate with visible light, also heats with infrared radiation. This internal environmental factor is an example of a device-device interaction that can contribute to such an occurrence as neonatal hyperthermia or burn.

Internal

The sun illuminates the external environment, and its radiance in the room may influence thermal balance. In addition, the television transmission tower located on a nearby hill can cause electromagnetic interference with the devices in the NICU (see Figure 64-1).

Patient

The patient can contribute to an accident in several ways (Kenney, 1983). An active patient can adversely affect the functioning of a device or interfere with a device's operation. A passive patient may be more or less susceptible to an injurious element of a device's function simply by virtue of age, weight, height, or physical condition.

Active (Educated; Uneducated)

An active patient may, for example, attempt to get out of bed even though bed rails are up. Sliding out of bed and entrapment of the head and neck can occur. The size, weight, age, and level of awareness of the patient are all factors that can influence the odds of

entrapment. The active, uneducated patient may, for example, change the controls of a ventilator on which he or she depends.

In one example, a side panel of an infant radiant warmer was left in the down position as shown in Figure 64-1, either from failure of the nurse to reposition it or because of failure of latches to secure the panel. This action contributed to an active neonate falling off the mattress surface and onto the floor.

Passive

A passive patient, simply by virtue of the patient's physical condition, height, weight, age, and mobility, may contribute to an accident. For example, a passive critically ill, low-weight, premature neonate whose hand is exposed to an elevated heat source is less likely to tolerate the thermal load because of impairment of peripheral circulation that can disperse the thermal energy absorbed by the hand.

Investigation Procedures

While no two accidents are exactly alike, investigation procedures include several well-defined steps, described as follows. Variations in each step may be necessary depending on the particular circumstances (see Shepherd, 1993; Bruley, 1994).

First Response

Clinical engineers should respond immediately to the scene of the accident, and should take the following steps:

- Prevent or minimize further injury or damage to patients and staff.
- Establish a perimeter.
- Check for damage to ancillary devices and facilities.
- Photograph, sketch, record, and otherwise document the scene.
- Obtain first-hand witness accounts.
- Begin to establish a spatial frame of reference and a time line.
- Preserve and sequester evidence.
- Launch investigation.

Examining the Scene

Arrive at the scene as soon as possible. Time is of the essence as environment changes. There is often a haste to clean up, bring in replacement equipment, and dispose of packaging material that could establish the identity of a disposable such as an electro-surgical pencil or a grounding pad. Search the trash for discarded wrappers and package inserts.

Establish initial conditions and record these by means of photographs, drawings, and notes. Photographs of the injury immediately after occurrence and subsequent photographs over time can be helpful in determining the nature of the injury especially in the case of skin lesions of unknown origin. A laboratory notebook or equivalent means of recording data should be used. Notes should be taken in ink rather than pencil. A medical device incident investigation form serves well as a checklist for obtaining information. The investigator is encouraged to develop a form, based on the following list of items that would typically be acquired in the course of a site inspection:

Incident Investigation Checklist

- Device information (manufacturer, brand name, model/catalog number, serial number, lot number, hospital control number, and labels)
- Maintainer information (service history)
- Event information (date, injury, date and time of awareness of event, date of reports to manufacturer/FDA, location, use as intended by manufacturer, and description of the event)
- Patient information: Name, address, phone, classification (inpatient, etc.), patient ID number, room number, age, weight, sex, physicians who treated them, and their medical condition before and after the event
- Injury information: Description, time of injury discovery, time of device application, locations of device and patient, treatment
- Incident investigation procedure: Initial conditions, e.g., control settings, environmental conditions, device history, relative position of device, patient, disposables, personnel, furniture (sketches and photographs); witnesses; documents (e.g., labels, service records, manuals and photographs of scene, devices, patient injury; tests performed; and findings).
- Investigation conclusions: How the device contributed to the event, and to what extent

Notes and sketches made at this time will aid in later reconstruction efforts. Space may be made available on the accident investigation form, or the notes and other documents may be attached to the form.

Note locations of all items in the vicinity, e.g., instruments, medical devices, disposables, carts, beds, furniture, personnel, visitors, documentation, manuals, labels, and package inserts. If items were moved after the occurrence, ascertain their location prior to moving. Failure of a device to operate in a safe mode may have been caused by its proximity to another device (see Chapter 60 for interactions between medical devices) that may have emitted electromagnetic interference. (see Chapters 62 and 63). Observe and note all instrument settings, control knobs, meter readings, and connections. Settings should not be changed unless necessary in order to prevent further injury to the patient. For example, the author investigated one accident in which several of a newborn's fingers were burned and eventually lost. The first response of the nurse and doctor was to remove

the source of heat (excessively high temperature humidified air delivered by a hose next to the fingers) from the fingers and to lower the temperature setting on the heated humidifier. These actions, recorded in the medical record and memorialized in witness statements, assisted the author in determining the cause of the injury.

Determine the identities of all witnesses, including doctors, nurses, technicians, physical plant maintenance personnel, housekeeping staff, visitors, respiratory therapists, and students. These individuals may have altered the position of devices, damaged line cords or connectors, or altered settings. See Chapter 95 for a discussion of a line cord entrapment caused by the hospital housekeeper who moved a motorized parallel bar in order to clean the floor and entrapped the cord in the process. Later activation of the bars resulted in a near-lethal electric shock. Also contact personnel who might not have witnessed the accident, but who might have been in attendance at some time or who might have other information to contribute (e.g., a person who performs the same kind of work in other areas of the hospital).

Note the environmental conditions such as time, temperature, and relative humidity. Note the conditions of the facilities upon which the device operation depends, such as line voltage, medical gas pressures and flows, water pressure and flows, and suction. Certain environmental conditions could adversely affect the operation of devices.

During this initial response, one should begin to establish a spatial-temporal relationship of significant events involved in the accident. (See Table 64-1.) Police reports, medical records, witness statements, depositions, and interviews may provide data for the time line. Typically, different observers have varying perceptions and recollections of time and space. These perceptions tend to be less clear with the passage of time. Obtaining evidence and facts as early as possible will minimize the effect of fading memories.

Evidence

The investigator must identify, document, examine, and preserve all evidence at the scene. A thorough search must be conducted, including a search of the trash for items that may have been discarded. The evidence should be labeled, photographed, placed in a suitable container, and impounded. Access to the evidence should be controlled and all parties who subsequently examine the evidence should be recorded to establish a chain of custody. Testing of all evidence may not be possible at the time of the initial response to the event. Proper identification and preservation will permit examination at a later date by the investigator or other parties.

In cases of serious injuries or deaths, examination of the device in question should be performed in the presence of all interested parties, e.g., the hospital representative, device manufacturer, and independent investigator.

Preservation

The investigator must take care not to do destructive testing or to damage the evidence in any way. The outcome of legal proceedings that may occur subsequent to the accident can hinge on the issue of spoliation, i.e., alteration of the evidence. Impounded evidence, such as a medical device, should not be placed back into operation until all parties have had an opportunity to examine it. The personnel who are responsible for routine maintenance and repair should not inspect the device. They may attempt to conceal errors committed previously during servicing visits.

Once notified, a manufacturer will typically ask that the device be returned for examination or that a manufacturer's representative be permitted to examine it in the hospital. The manufacturer may repair or replace a defective component, and issue a report that the device was found to have no defects. Manufacturers have occasionally claimed that the returned device never reached its destination. One should not send a suspect device to the manufacturer without a written agreement as to the actions to be taken during a device inspection. Such an agreement should address the following points at a minimum:

- Description of product (e.g., serial number, hospital equipment control number, lot number)
- Description of malfunction
- Request to examine for defects
- Letter to notify sender upon receipt of device
- Request for report within 30 days of a finding, with conclusions and recommendations
- Description of test methods
- No destructive testing without prior permission
- Prompt return of device upon completion of testing or sooner if necessary
- Chain of custody preservation such as transportation records

Should destructive testing be necessary by the manufacturer, it should be done in the attended by a representative of the hospital and the injured party.

Requests from the FDA to test the device should not be granted unless approved by the hospital's legal counsel. The ability to have the device tested by an independent party may be adversely affected and evidence could be lost.

Documents

All pertinent standards, manuals, incident report, medical records, notes, maintenance records, test results, and labels should be obtained. Investigators should also obtain instructions, technical communications, and warnings, analyze any warnings. Product liability lawsuits often allege failure to warn and provide appropriate safety information (Peters and Peters, 1999).

Documents upon which the investigator may rely upon include standards and guidelines related to performing investigations (ASTM, 1995; ASTM, 1996; ASTM, 1997 and 1997a; ASTM, 1998; IEEE, 1985) and other standards such as the Standard for Health Care Facilities, NFPA 99 (NFPA, 2002), and National Electrical Code. NFPA 70 (NFPA, 2002a), and the National Electrical Safety Code (IEEE, 1997). See Section XI of this Handbook for more information on standards and regulations. Other documents include

hazard alerts, recall letters, manufacturer specifications, design and testing documents, and post-market surveillance databases, e.g., the FDA Manufacturer and User Facility Device Experience Database (MAUDE).

The reliance upon standards becomes especially important should an investigator's findings be challenged in a court of law. Recent court decisions beginning with *Daubert v. Merrill Dow Pharmaceuticals* have placed increased responsibility upon judges to scrutinize the bases for the opinions of experts (Babitsky et al., 2000). Whether or not standards exist for an investigative technique's operation is one criterion applied. The peer review to which a method or technique is subjected during the standards development process and the existence of the standards themselves can be the key to admissibility of evidence (Lentini, 2001).

Examination of Evidence

Measurement techniques, inspection and measurement tools are described as follows.

Measurement Techniques

Use the human senses: Sight, hearing, smell, taste, and touch to examine evidence. If one possesses a sixth sense, use that as well.

Testing of devices should not be done in isolation on a laboratory bench, but ideally at the location where the accident occurred, or in the context of a reasonable reconstruction of the scene. A device might perform satisfactorily on the test bench in the laboratory but not when tested in the environment where the injury occurred. Factors such as electromagnetic interference from another device or from an outside source, a power line irregularity in the patient's room, or a gas source providing inadequate pressures and flows could contribute to a device's inadequate performance.

All available devices involved in the accident should be inspected, along with all disposables, accessories, packaging, and peripheral devices. The facility should be inspected as well, and the output of electrical receptacles and medical gas outlets should be measured if these were used. Weather conditions should be noted—a lightning strike may have caused a momentary interruption in power or a power line transient that adversely affected devices. If weather details are unknown, the United States Meteorological Survey can provide the weather conditions from the time in question.

During a site inspection, take photographs of everything examined. Photographs of the scene should be taken from all directions. The front, back, sides, top, and bottom of the device or devices should be photographed. Take close-ups of relevant components such as controls, meters, and connectors. Dimensions of the object photographed can be seen if a ruler is placed in the field of view. Record the subject matter in each photograph in a laboratory notebook. Record a sketch of the scene in the notebook and note the photographic frame, using an arrow to show the camera angle. Pay special attention to damage, which could be a sign of physical abuse or of unusual connections, improper settings, or incompatible accessories.

Physical measurements include temperature, relative humidity, time, electrical parameters, dimensions, and weight. Note a device's construction materials. Use a magnifier—at times, the smallest bit of evidence, such as a tiny metallic whisker that causes a relay to fail, provides the greatest clue. Take macro photographs to capture such details.

While it is beyond the scope of this discussion to present all testing procedures, functional verification of device performance includes the following:

- Therapeutic devices should be operated to determine and measure their output, e.g., energy, waveform, frequency, irradiance, direction, flow, pressure, and volume.
- Diagnostic devices can be tested for performance by using appropriate simulators for such physiological parameters as blood pressure, temperature, and QRS waveform.

Testing a device is best done in an environment that replicates the actual environment at the time of the accident as closely as possible. Failure may have occurred due to an interaction between the device and another device in the environment or to some abnormality in the facility such as line voltage variation or electromagnetic interference. One must always be on the alert for the possibility of an intermittent failure that occurs only under particular circumstances.

Inspection and Measurement Tools

An accident investigation kit should be available at an instant's notice. Figure 64-5 shows the "yellow safety box" used by the author in his investigations (Dyro, 1995a). Figures 64-6 to 64-9 show the items stored in the box. Other items may be added depending upon the nature of the event to be investigated.

Reconstruction

When possible, attempt to reconstruct the accident. Experiments can be performed to simulate the event if the appropriate exemplars can be obtained and if enough is known about the spatial and temporal relationships of the event. Use simulators if, for example, a physiological signal such as ECG or temperature is required. Photographs and video recording of the simulation will help interpret the results.

As an example, the steps to take in accident reconstruction for electrical injury cases is as follows (Fish and Geddes, 2003):

- Determine current flow
- Determine expected medical effects of the electrical current
- Determine the nature of the injury actually sustained
- Compare the expected effects of current flow on the actual injury
- Consider that the person's condition is due to disease or other processes unrelated to the electrical injury
- Cite references from the scientific literature that support and illustrate the consultant's opinions

Figure 64-5 The author with his yellow safety box entering a client's home prepared to perform an accident investigation (Dyro, 1998).

Figure 64-6 The yellow safety box, shown open with its two trays removed to display their contents.

Figure 64-7 The contents of the upper tray. Upper row from left to right: tape measure, photographic film, Swiss army knife, Leatherman® tool, 30X illuminated magnifier, electrical circuit voltage tester and live circuit checker, letter scale (0-100 gm), micrometer. Lower row from left to right: Post-It notes, ball point pen, marking pen, jeweler's screwdrivers, screwdrivers (large and small flathead), receptacle tester, force gauge, flashlight.

Figure 64-8 Contents of the lower tray. Upper row from left to right: wire strippers, forceps, batteries, adapter, electrical flasher, and Allen wrenches (metric and English). Middle row (l to r): curved tip pliers, needle nose pliers, scissors, Atomic Fireballs (candy to distract curious children during home investigations), camel hair brush, electrical grounding strap, 10X magnifier, inspection mirrors (large and small). Lower row from left to right: assorted syringes, plastic collection bags, cotton swabs, and screwdrivers (Philips head and small flathead).

Figure 64-9 Contents of the bottom of the box. Upper row from left to right: leads, thermocouples and adapter, multimeter, sound level meter, and camera. Lower row from left to right: physiological simulator, examination gloves, micrometer, masking tape, electrician's tape, calipers, tripod.

The established spatial-temporal relationships aid in the reconstruction. These relationships are first documented in the initial response to the accident, sometimes in a spreadsheet format. An example of how such a document can be formatted appears in Table 64-1.

Interaction with and Interviews of Others

Interview Techniques

The CE should also be aware that during a time of an accident witnesses are typically under increased stress and may not have accurate recollections of events, times, and other personnel who may have been present. Some personnel may also attempt to conceal information that could implicate themselves or others in contributing to the injury. Ask open-ended questions, allowing the person interviewed to answer in his or her own words. Details such as movement and location of personnel, and observations such as smells, sounds, and sights should be ascertained and explored. The clinical engineer should adhere as closely as possible to the following guidelines for conducting a fact-finding interview:

- Question one person at a time, to avoid uncomfortable interpersonal relationships (peers, subordinate/employer).
- If several people are involved in an equipment setup, interviewing them together may be helpful.
- Understand how the position of the person interviewed may influence answers to questions.
- Be prepared with technical details and a list of questions.
- Remember to determine who, what, where, why, and how.
- Take notes while maintaining eye contact, refrain from audio or video recording.
- Ask questions to put the interviewee at ease.
- Keep an open mind.
- Do not jump to conclusions: Note discrepancies, and defer judgments until all interviews have been done.
- Do not interrupt an answer to ask for more details.
- Ask open-ended questions so that the person tells a story; even seemingly irrelevant details may prove to be important after all the data have been collected.
- Ask questions to elicit observations rather than judgments.
- Rephrase response to ensure that the answer is understood.

Table 64-1 Accident reconstruction spread sheet. The format shown in this spreadsheet may be changed depending on the nature of the event under investigation

Person	Source	Facts and statements	Date & Time	Significance
Buckley	NE Weather Science	Relative humidity (RH)=90%; Temperature (T)=98°	1/16/2 11-12 PM	Perspiration of foot in shoe, sweat on hands
Cragin	Deposition page 10, line 5	"The floor is wet all the time."		Increased conductivity
Allen	Affidavit 5/12/2	"The lights flickered."	1/16/2 11:05 PM	Power line disturbance
Svenson	Service Report #8098	Short circuit repaired	1/17/2	Faulty device

- End each interview by emphasizing the role of improving quality through root cause analysis.
- Summarize notes and sign and date the document upon conclusion of interviews.

Witnesses and Other Hospital Personnel

All eyewitnesses should be interviewed, in addition to any personnel that may have relevant information, such as technicians and any service personnel responsible for cleaning, sterilizing, inspecting, and maintaining the items used at the time of the injury.

Manufacturers

The device manufacturer must be notified in accordance with FDA medical device reporting (MDR) regulations (Guyton, 2002; FDA, 1996).

FDA

Discussions with the FDA should be coordinated with the hospital administration's FDA contact person.

Attorneys

All discussions between hospital staff and attorneys must take place with the advice and consent of the hospital legal affairs office.

Media

The hospital clinical engineer should not speak to the media, e.g., radio, television, and newspapers. Any contact with the media should be limited to the official hospital spokesperson. The clinical engineer should be aware that information transmitted to the media may not be disseminated in a way that reflects all the information deemed importance or significant (Dyro, 1998a).

Reports

Upon completion of an investigation, a written report is prepared. Reports should be well written, concise, complete, and accurate. The report should include of the following parts: Abstract, introduction, methodology, results, discussion, conclusion, opinions, root cause analysis, and recommendations. Use advanced techniques for report writing to make your report come to life. For example format it well, and use photographs, sketches, figures, and tables to help tell the story (Dyro, 2003).

Case Studies

Studies of several cases which the author has investigated follow. These illustrate one or more of the five elements in the system and the investigation techniques described above.

Infant Incubator

The author investigated a death at a large university teaching hospital. An infant died of hyperthermia. The temperature of the infant incubator (Figure 64-10) was 108° F when checked by a nurse at 2:00 a.m..

Investigation revealed that the operator, environment, and the device itself (both from a manufacturer and maintainer perspective), contributed to the death.

Operator

User abuse (abuse) is illustrated in the four views of the incubator shown in Figure 64-11. The figure shows obvious signs of rough treatment at several points of the incubator. Bent control knobs, a cracked meter face, and a bent carrying handle are clearly shown. The nurses were both inattentive and uneducated. They failed to observe these signs of mechanical shock and failed to recognize the possible consequences of such physical damage.

Environment

The environment in which this event occurred was a nursery and the event occurred during the night shift about 3:00 a.m. At this time, the nurse was inattentive to her duties and failed to check on the neonate.

Device

The maintenance of the incubator was deficient because the hospital had no clinical engineering department, and the incubator was not under any kind of a service agreement with an outside party.

No incoming inspection or periodic inspection had been performed that may have detected the design inadequacy and certainly would have detected the signs of user abuse.

The device design was defective. The forces to which the control unit and incubator are typically subjected were not considered, and the thermostat system was inadequately equipped to handle these forces. The backup, high temperature, mercury-in-glass thermostat failed because the design did not consider the typical rough handling of the control unit. Mechanical shock and vibration separated the mercury column. Because the column was broken, it did not form a conductive pathway between the two circumferential electrodes on the exterior of the glass thermostat capacitively coupled to the column (Narco, 1982; Harding, 1982; Haffner, 1982; Dyro, 1977) (see Figure 64-12).

As a result of recommendations made by the author, the hospital instituted a clinical engineering department.

Ventilator and Apnea Monitor

A young child died at home in bed while on a ventilator and while monitored by a heart rate and respiration monitor (Dyro, 1998). The breathing circuit became dislodged from the tracheal tube. The ventilator low airway pressure alarm failed to activate because the patient connector of the breathing circuit was occluded by the child's neck. The ECG/respiration rate monitor failed to alarm because it detected artifact ECG and respiration signals generated by the mechanical force of the ventilator tubing against the child and the bed (Sahakian et al., 1986). With each ventilation, pressure generated in the patient circuit was conducted to the bedside monitor arrangement, causing movement of the transthoracic electrodes. This motion prevented the monitor from alarming. The monitor and ventilator were plugged into an old power strip that the parents had found in their garage. The power strip was faulty, and its neon light "on" indicator circuitry produced electromagnetic interference that resulted in artifact signals detected by the monitor. Reconstruction of the event was possible because all of the components of the system or appropriate exemplars were available.

All five elements of the system described above were involved in this event: The ECG/respiration rate monitor (device), ventilator (device), patient circuit (device), child (patient), facility (power strip), environment (bed), and the parent who assembled the equipment (operator).

Skin Lesions

The investigator will on occasion be asked to investigate an event that resulted in a skin lesion. Often the investigator will be told that the patient received a burn. Care must be taken in the interpretation and investigation of injuries that are described as burns. It is natural to think of a burn as an injury to the skin caused by excessive heat. However, the investigator must consider all the mechanisms that can produce a skin injury (Gendron, 1988). Table 64-2 provides a list of several of several devices that led to skin lesions as a result of several different injury mechanisms. Device, injury, and mechanisms are shown in the table.

Serious burns have occurred in at least two incidents that the author has investigated in which neonates in incubators crawled from the mattress surface to hot air vents (Figure 65-13). Missing barriers and excessive temperatures emanating from air vents

Figure 64-10 The infant incubator under test. A monitor with air temperature sensors measures the thermal characteristics of the incubator.

A

B

C

D

Figure 64-11 A–D Four views of control panel of incubator showed many signs of rough handling such as bent knobs (A, B) and handle (C) and cracked meter face (d).

presented a hazard. The active infants were able to move over the vents. Inattentive nurses failed to observe the movement of the infant to the areas of the incubator at dangerously high temperatures. In one instance, the manufacture issued an advisory letter indicating that a modification kit was available to isolate the infant from the source of heat, but the hospital failed to receive the letter, and the modification was not made.

Accident Investigation Education

Learning about accident investigation techniques can occur as part of college courses, or during workshops, seminars, or teleconferences, and in the workplace.

Formal Courses

Formal courses in the clinical engineering curriculum should be developed to include accident investigation education. This chapter can be used as an outline around which to

Figure 64-12 The backup thermostat is shown with the broken mercury column.

Table 64-2 Several examples of incidents involving skin lesions investigated by the author are listed in terms of devices and types and mechanisms of injury.

<i>Medical device</i>	<i>Injury</i>	<i>Mechanism</i>
Heating pad	Infant whole body burns	Thermal (conduction)
Infrared lamp	Adult skin burns	Thermal (infrared Radiation and conduction)
Operating room table mattress	Whole body lesions	Chemical (ethylene oxide sterilant) burns
Heated humidifier	Infant face burns	Thermal (conduction and convection)
Electrosurgical unit in oxygen enriched atmosphere	Face and upper body burns	Oxygen enriched OR fire thermal (fire)
Infant radiant warmer	Lower body burns (white tape defeated alarm)	Thermal (infrared radiation)
Electrosurgical unit	Burns to chest; Burns around mouth; Internal burns	Thermal (electrosurgical current)
Portable oxygen unit	Burns to legs	Thermal (fire)
Pulse oximeter skin electrode	Skin lesions	Thermal (conduction)
Surgical retractor	Skin and muscle damage	Pressure necrosis

develop a course on accident investigation for the clinical engineer. Examples follow for classroom techniques, case studies, demonstrations, examinations and reports that should be included in a formal college course. The course length and depth can be adapted to the educational requirements of the class. Undergraduate and graduate courses in clinical engineering should include at least six hours of class lecture and six hours of preparation.

Classroom Techniques

The instructor should develop systems approach skills by creating a hypothetical situation involving a specific medical device. The students should be directed to describe the system with a drawing. The student should strive to incorporate all five elements (device, operator, facility, environment, and patient) into the drawing and analysis. Each element should contribute in some way to the cause of the accident. The class should be given a list of devices from which to choose, such as infant incubator, ventilator, anesthesia machine, EKG machine, electrosurgical unit, hyperthermia unit, infusion pump, defibrillator, and physiological monitor. After completion of the exercise, the student should present the hypothetical case study to the class, using the graphic he or she created.

Case Studies and Demonstrations

Lecture presentations of actual case studies are more relevant and hold student interest better than hypothetical cases. Classroom and laboratory demonstrations with actual medical devices reinforce understanding of device interactions with other elements in the system.

Examinations

The examination for the certification of clinical engineers administered by the American College of Clinical Engineering includes questions on accident investigation. The candidate for certification is expected to answer multiple choice, essay, and oral questions during the examination process.

Reports

Good communication skills include writing skills. Students should learn how to write a technical report that is accurate, concise, and complete and includes the basic elements: abstract, introduction, methods and materials, results, discussion, and conclusions. Reports should contain references to supporting documents, such as hospital standards and operator and service manuals. Techniques to make a report more effective, such as good formatting and the use of photographs, diagrams, figures and tables should be emphasized (Dyro, 2003).

Informal Courses and Independent Study

Everyday occurrences in the home provide the opportunity to practice accident investigation. If a home appliance, e.g., radio, television, toaster or dishwasher, operates in an unexpected fashion, the clinical engineer should use this event as an opportunity to practice and refine investigation techniques. In addition to technical and scientific texts on subjects related to accident investigation. He or she can obtain additional insight from television and film in which plots involve forensic examination techniques. The CE will find, however, that all the clues necessary to establish the cause of the adverse event may not be present in reality as they always seem to be in novels, movies, and TV.

Resources to assist in accident investigation education and training are available from many sources, including the following:

- Standards

American Society for Testing and Materials
 Association for the Advancement of Medical Instrumentation
 National Fire Protection Agency
 Institute of Electrical and Electronics Engineers
 Chapters 117 and 120 of this handbook

Figure 64-13 The author positions thermistors to measure the temperatures of surfaces and air within an infant incubator.

Figure 64-14 Surface temperature thermistors and an air temperature thermistor are shown affixed to surfaces and suspended above the air inlet vent of infant incubator in which infant suffered third-degree facial burns after contact with heated, humidified air at excessive temperatures. The hospital had not installed the plastic shield that the manufacturer made available as a retrofit.

The Great Debate on Electrical Safety—In Retrospect

Malcolm G. Ridgway

Sr. Vice President, Technology Management and Chief Technology Officer, MasterPlan Inc. Chatsworth, CA

The 1960s saw both the advent of open-heart surgery and the increasing use of cardiac catheterization procedures. More and more patients with externalized transarterial catheters, usually enclosing leads that could be quickly connected to an external cardiac pacemaker, were appearing in the new cardiac care or special care units of hospitals. Once physicians realized that this highly conductive pathway not only bypassed the usually protective layers of relatively resistive body tissues, but that it also directed current to the most electrically sensitive areas of the inner walls of the heart, concerns arose about the possibility that these patients could be electrocuted by currents much smaller than those that would affect the exterior of the body.

Patients with externally accessible conductive pathways leading directly to the heart came to be known as electrically susceptible (ES) or electrically sensitive patients (ESPs). The theoretical phenomenon, in which an ES patient might be induced into fatal ventricular fibrillation by the passage of a small level of current through the transarterial catheter, became known as "silent electrocution" or "microshock."

Concerns about this potential scenario were published as early as August 1961 in an editorial in the journal *Circulation* titled, "Hidden Hazards of Cardiac Pacemakers." Laboratory experiments indicated that the levels of current that could trigger potentially fatal ventricular fibrillation were indeed significantly lower than the levels associated with conventional electrocution—on the order of tens of microvolts. Tests also established that the now-familiar phenomenon of current "leakage," as well as the process of relatively

large currents passing through low resistance grounding conductors, could easily send high magnitude currents into the exposed conductive pathways.

The concept of equipotential grounding, in which substantial (green) grounding conductors are used to connect all exposed conductive surfaces to a central grounding point in a star configuration, was developed as a prime defensive measure against this new hazard. Others championed the use of isolation transformers as the best way to reduce leakage current in the ground circuits of the hospital's electrical distribution system. Several regulatory and standards-setting organizations began taking notice.

In April 1968, the division of medical sciences of the National Research Council (NRC) held a two-day workshop on "Electrical Hazards in Hospitals" that was attended by more than 100 people. The proceedings of this workshop were edited by Dr. Carl Walters and later published by the influential National Academy of Sciences (Walter, 1970). Carl Walters was a renowned surgeon at the Peter Bent Brigham Hospital in Boston, a member of the faculty at Harvard Medical School, and chairman of the committee on hospitals of the National Fire Protection Association (NFPA). Dr. Walters has been credited with establishing one of the world's first blood banks in a basement room at Harvard in 1934, and later (1949) with the invention of the blood bag, which ended the cumbersome and dangerous procedure of pumping blood directly from donor to patient via parafin coated glass tubes. In addition, his insight and pioneering work with the Castle company led to the introduction of high pressure steam sterilizers (sometimes called

autoclaves) for reprocessing surgical instruments. Before the autoclave, surgical instruments were simply "sterilized" in boiling water.

At the 1968 NRC-sponsored workshop, Dr. Walter first speculated on the probable incidence of death by "microshock" in US hospitals. The following is a statement he made during a discussion of the national statistics on electrocution that were available at the time:

"As Chairman of the Committee on Hospitals of the National Fire Protection Association, I sought to convince the NFPA to broaden the scope of the Committee's responsibilities. An insurance actuary, whose statistical hobby is electric shock and electrocautery injuries, assured me that there were 1200 misdiagnosed electrocutions annually in hospitals during 1964 and 1965. That amounts to a "misadventure" annually in one of seven hospitals in this country. These were classified as cardiac arrest. But the deaths occurred during resuscitation efforts unrelated to the patient's primary disease or during application of electric appliances. These were culled to demonstrate prevalence and also to show why the medical profession has not recognized the problem. During a lifesaving venture, those involved may not perceive what is going on. I have encountered three such instances in a recovery room. When the situation is recreated, you can see exactly which device is causing the trouble. There are a dozen or so astute analyses in the literature that describe similar settings. Now the profession is becoming cognizant of the problem; that is why so many doctors are interested in electric shock."

On January 27, 1969, a report titled, "Accidental Electrocutions Claim 1200 Patients a Year" was published in *Electronic News* (Electronic News, 1969). The report quoted microshock statistics obtained from Dr. Walter during a telephone interview. These same statistics were repeated again during presentations made by Dr. Walter and others at the 71st Annual Meeting of the American Hospital Association in Chicago in August 1969. After the proceedings of the NRC workshop were published in 1970, these statistics were repeated at a press conference and widely reported throughout the national press.

In June 1970, a report was distributed by the UPI wire service that Ralph Nader, an attorney and consumer activist, had alleged in a speech that 5000 deaths attributable to microshock occurred each year in the nation's hospitals. To this day Mr. Nader has not provided any independent substantiation for his figure.

In March 1971 the *Ladies Home Journal* ran an article quoting Ralph Nader titled, "Ralph Nader's Most Shocking Expose," which stated that, "at the very least, 1200 Americans are electrocuted annually during routine diagnostic and therapeutic procedures," and that "medical engineers such as Professor Hans von der Mosel, co-chairman of the Subcommittee on Electrical Safety of the Association for the Advancement of Medical Instrumentation and safety consultant to New York City's Health Services Administration, believe that the number might be ten times as high as the conservative estimate of 1200" (Nader, 1971). This is the source of the sometimes quoted "estimate" of 12,000 deaths per year. Interestingly, this same article states that, "Only three hospitals in the country have biomedical engineers on their staffs to supervise the operation and maintenance of complex machines: Downstate Medical Center in New York City; Sinai Hospital in Baltimore; and Charles S. Wilson Hospital in Johnson City, N.Y."

By the mid-1970s, the NFPA's Committee on Hospitals had developed and distributed for public comment some proposed amendments to Article 517 of the 1971 edition of the National Electric Code (NEC) that would require all hospitals to have isolation transformer-based "Safe Patient Power Centers" in all special care areas of the nation's approximately 6000 hospitals. The potential financial impact of this proposal shocked the health care community. The technical inadequacy of the proposed solution also shocked the embryonic clinical engineering community.

In the spring of 1971, shortly before the Annual NFPA Meeting in San Francisco at which the Committee on Hospitals' proposed amendment would be voted on, the Hill-Burton Program Committee convened a private meeting in Rockville, Maryland, at which ten experts in "electronics in hospitals" were invited to debate with Dr. Walter and his technical advisors about the merits of the proposed new requirements. A written report generated by one of the ten experts summarized part of Dr. Walter's presentation at that meeting as follows:

"Dr. Walter's 'estimate' of 1200 deaths per year due to microshock had come about in the following way. In 'his' hospital in Boston, a patient died under circumstances leading to his belief that the death was due to electrocution from microshock. Dr. Walter estimated that "his" hospital cared for about one in 1200 of all US patients yearly. Multiplying one suspected death by 1200 resulted in his widely reported estimate of 1200 deaths per year."

Participants at the meeting indicated that the proposed solution was technically inadequate because the isolation monitor, that the National Electric Code required to be used with an isolation transformer, injects far more current into the circuit than the "safe" level of 15 microamps. Dr. Walter's team was unable to rebut the criticism. The report goes on to state that, "The Hill-Burton Program Committee's findings were never publicized, but the committee did inform the NFPA that if isolated power in all special care areas was required by the NFPA in its forthcoming standards, the committee would terminate its long-standing requirement that hospitals receiving its funds comply with NFPA's standards." This was a substantial threat—at that time virtually all new hospital construction and renovations were subsidized with federal funds from the Hill-Burton Program.

When the proposed amendments to the NEC were presented at the NFPA Annual Meeting in San Francisco in May 1971, they prompted a very lively floor debate, after which adoption was deferred and they were returned to committee by a 106 to 38 vote of the membership of the electrical section.

In spite of this period of spirited discussion about the reality or non-existence of this new, perhaps life-threatening hazard, and the uncertainty about whether or not the various proposed countermeasures and elaborate safety tests could eliminate or reduce the threat, a battery of new electrical safety requirements appeared. Many of these requirements persist today in only slightly modified form as part of various regulations. The Joint Commission on Accreditation of Hospitals issued new standards that prescribed quarterly

documented electrical safety testing for all of a facility's patient care equipment. In California, the State Department of Health issued stringent electrical safety measures as part of its new requirements for general acute care hospitals. Title 22 of the State Administrative Code introduced the soon-to-be-obsolete concept of the "electrically sensitive patient" and a host of related tests. It was a time of absurdities, such as festoons of green grounding wires connecting every piece of exposed metal surface within the vicinity of any special care bed (even in the adjacent bathrooms) to substantial central grounding posts. However, diligent, dedicated investigations over the next several years for possible occurrences of microshock failed to turn up any credible evidence that this ingeniously conceived but still theoretical hazard was claiming any lives.

In September 1973, Dr. Joel Nobel, Director of the Emergency Care Research Institute, made a statement during hearings before a Senate subcommittee on the proposed Medical Device Amendments of 1973:

"The issue of microshock electrocution, its real versus claimed incidence, its widespread publicity, the enactment of codes and laws to combat it, and the economic fortunes of the electrical transformer industry, are inextricably intertwined. Phony statistics have been used to promote the sales of safety equipment and manipulate the National Electric Code to require the use of specific products. We are not suggesting that the microshock electrocution issue was fabricated by the industrial and code making camps and consumer advocates. Each, however, capitalizing on the issue, has distorted both the technical problems and the priorities rather badly. The result is that many millions of dollars have been diverted from more critical areas of health care. This electrical safety issue has, however, performed a useful catalytic function in drawing attention to other problems associated with the use of technology for health care. It has helped hospitals to understand the broader needs for engineering support of patient care, including the judicious purchase, inspection, and preventive maintenance of medical equipment."

In later testimony, he added: "Our information and priorities are sometimes distorted by special interest groups, however, and this is acceptable. By way of example, consider how much attention has been devoted to the problem of electrical safety in hospitals during the last 5 years, especially by the engineering community and the manufacturers of safety devices and equipment. Speculation is often translated into reality, or at least belief, by the very fact of statement or publication. Bogus statistics on electrocution in hospitals have been proclaimed and republished without end or confirmation, for 5 years. Many millions of words have been written about microshock and many millions of dollars spent to avoid it. It is obvious, however, that we still know nothing of its real incidence. Is it a widespread problem or a phantom? We are not suggesting that the electrical safety problem is nonexistent. Our data show that it does exist, and it is significant; but its characteristics and magnitude are rather different than is generally believed. Our biggest problem is not electrocution by microshock but, instead, inadequate or unreliable power. Not too much electricity but too little."

And in August 1975, the following report appeared in the journal *The Medical Staff* under the heading, "The Myth of Iatrogenic Electrocution: Its Effect on Hospital Costs."

"A decade or so ago, a well-known surgeon made the widely publicized statement that there were 1200 electrocutions a year in US hospitals. The charge appeared regularly thereafter in the lay press. Evidence supporting the charges has never been produced."

At the AMA annual scientific assembly in Atlantic City in Jun, 1975, John R. Bruner, MD, assistant professor of anesthesia, Harvard Medical School, stated flatly that 'contrary to erroneous, if not willfully fabricated, reports in family magazines and the press, there has been no documented death due to electricity in a US hospital in more than a decade.' Dr. Bruner admitted that he was among those who raised the specter of iatrogenic (physician-caused) electrocution nearly a decade ago. 'Since then' Dr. Bruner said, 'there has developed little evidence to support fears that silent electrocution is a common occurrence.' He said that fear has led to the discarding of useful equipment in favor of 'safety featured gadgetry at much greater costs. Bureaucrats and inspectors, whose good intentions exceed their knowledge, insist that clinical care areas be festooned with green wires like charms to ward off evil spirits. And isolation transformers and fancy wiring are foisted upon the medical consuming public at great expense.' He saw no safety benefits in these escalating costs since 'the magnitude of the hazard was largely imaginary in the first place.' He did stress that there is potential for injury wherever electricity is used. He said that haste, stress, and moisture, depending upon the special characteristics of the medical situation, may further enlarge the opportunities for injury to the patient around whom multiple appliances are commonly clustered. 'Electrocution occurs when, and only when, an individual becomes the component that closes the circuit in which a lethal current can flow,' Dr. Bruner said."

In the meantime, someone had—with a stroke of genius—realized that this entire threat could be completely eliminated by simply protecting the exposed conductive ends of the patient's catheter. Proper terminations for transarterial catheters providing low impedance pathways to the heart and great vessels became the order of the day, and electrically sensitive patient's need for special environmental consideration disappeared almost overnight. Articles on electrical isolation of the patient appeared. See, for example, Guidelines for Clinical Engineering Programs; Part I: "Guidelines for Electrical Isolation" (Ridgway, 1980).

A byproduct of this extended episode, however, was the discovery that the existing quality of maintenance of the typical hospital's ever-expanding inventory of electronic equipment was inadequate. A new high intensity focus on equipment maintenance and safety was born.

Another interesting sidebar is the parallel, then subsequent, debate about the rationale for perpetuating the isolated power requirement in operating rooms where the use of flammable agents had been prohibited. The original requirement for isolated power had been introduced into the NFPA standards governing anesthetizing locations in 1941, along with other antistatic measures intended to reduce the number of accidents due to the ignition of flammable agents such as cyclopropane.

In 1970, the standard addressing anesthetizing locations (NFPA 56—Code for the Use of Flammable Anesthetics) had been renumbered as NFPA 56A and given the title “Standard for the Use of Inhalation Anesthetics (Flammable and Nonflammable).” According to this new document, anesthetizing locations where the use of flammable agents was prohibited did not have to install or use any previously required antistatic safeguards, except the isolated power system. In retrospect this might appear strange, until one considers the other issues faced by the NFPA’s Committee on Hospitals at that time. The committee was advocating the use of isolated power systems (IPS) in other special care areas of the hospital as a safeguard against microshock. The, often acrimonious debate continued throughout the 1970s and well into the next decade, documented in *Guidelines for Clinical Engineering Programs; Part IV: Isolated Power in Anesthetizing Locations? History of An Appeal*, (Ridgway, 1981). The IPS advocates finally settled for permitting isolated power in anesthetizing locations, but not requiring it. The debate was particularly interesting because advocates of the less stringent approach required considerably more professional courage and belief in their analyses than those advocating the “safer,” more extravagant solution. One approach that proved useful in bringing some uncertain observers around to the more radical position was the use of a probabilistic illustration to semi-quantify the level of risk, documented in *Guidelines for Clinical Engineering Programs; Part III: The Risk of Electric Shock In Hospitals* (Ridgway, 1981).

There have been no significant adverse trends in electrical accidents in operating rooms over the past 20 years. The predominant categories of equipment-related misadventures in the operating room continue to be patients accidentally burned by poorly implemented electrosurgical procedures, and patients injured by pressure sores resulting from extended contact with the unyielding surface of the surgical table. Both of these problems are often misdiagnosed as accidental burns.

Section VI

Education and Training

James O. Wear
Veterans Administration
North Little Rock, AR

The terms *education and training* are frequently used synonymously, but they have two very different meanings. Both require teaching and result in learning—but one is very broad and general, while the other is very specific.

Education develops a general competence in a field by fostering expansion of knowledge and wisdom. The best example of education is formal schooling—that is, a course or series of courses of formal study or instruction. Education consists of learning theories, philosophies, and how to obtain and use information. Synonyms for the word “educate” include develop, enlighten, illumine, enlarge the mind, fill with new ideas, and edify.

Training, on the other hand, is very specific. It exercises someone in a profession or directs them in obtaining a skill. Training involves giving instructions and drilling individuals in habits of thought or action. Training is used to shape or develop character of people by discipline or by precept. Synonyms for the word “train” include coach, drill, exercise, practice, and familiarize (e.g., we train soldiers, athletes, and animals).

A third word that is sometimes used synonymously with educate or train is teach. In teaching, one is providing lessons, lecturing, interpreting information, indoctrinating individuals, or influencing their behavior. In the process of teaching, one is attempting to cause a change in behavior; if the individual learns, then a change in behavior will have been accomplished. Teaching actually involves both education and training. It could involve only one of the two, such as a course called *Introduction to Clinical Engineering* or a course on *How To Use a PDA*. *Introduction to Clinical Engineering* would be education since it probably would not contain any specific skills; *How To Use a PDA* would probably be entirely training. In most cases, however, teaching does involve both education and training.

A college education is general education in a pure sense because most of what is learned, as far as specific information, is obsolete at the time it is learned or shortly after one finishes college. The result of a college education on a long-term basis includes only two things: An individual learns 1) how to think and 2) where to find information. With this educational background, one can then be trained to do the specific skills and jobs that must be accomplished.

The college education of an engineer contains more training than that of someone graduating from a College of Arts and Sciences. An engineer goes through many courses in which he learns specific skills. He learns how to make specific calculations so that when he graduates he is immediately able to perform some specific tasks. However, in our rapidly changing technology, even this ability is lost within approximately 3 years as he becomes obsolete without further education and training.

A clinical engineer may have additional training and education through an internship, either as part of his curriculum or after graduation. An internship is probably more training than education, but it does contain some of both. Once on the job, the clinical engineer must, as must any other engineer, go through lifelong continuing education or, one should say, continuing education and continuing training.

With rapidly changing technology, much that clinical engineers learn becomes obsolete in short periods of time and as new technologies come along. They may also find themselves going in new career directions. Clinical engineers attend professional meetings, short courses, and university courses, which may lead to advanced degrees. Training on specific equipment will be required, as well as learning new procedures and techniques. Continuing education activities may be formal or very informal, but both are necessary for a clinical engineer to continue to be well educated and well trained.

Academic programs in clinical engineering are at different levels. The Associate’s Degree programs that train Biomedical Engineering Technicians vary greatly in program content. Some are electronic technician programs with a course or two in biomedical equipment added, while others are more intense programs with internships. US undergraduate and graduate programs are mostly biomedical engineering programs rather than clinical engineering programs. There are very few clinical engineering programs in the U.S. Biomedical Engineering programs are more theoretical and equipment-design oriented whereas clinical engineering is an application hospital-based type of training activity. The key to any clinical engineering training is an internship. A clinical engineering department is typically hospital-based, like the one at the University of Connecticut, which is a general clinical engineering program with a one-year internship. Several programs, which are more commonly called rehab engineering, could be considered a

subspecialty of clinical engineering. They have internships in rehab programs and within hospital settings.

Clinical engineering programs are more highly developed at the international level, such as in Germany, Ireland, and Australia. The American College of Clinical Engineering, in conjunction with the World Health Organization and international clinical engineers, has developed programs in advanced clinical engineering workshops around the world primarily for developing and transitional countries, for engineers and administrators to learn about health care technical management. Dyro, Judd, and Wear summarize the programs that have been presented. Judd, Dyro, and Wear present an overview of an advanced clinical engineering workshop presented in Cape Town, South Africa and specifically tailored to encompass the area of health technology management. These workshops, in addition to providing educational opportunities for engineering and health care administrative personnel in target countries, have provided cross-fertilization in the international engineering field with involvement of faculty from different countries.

Continuing education of clinical engineers is important since they must keep current with engineering developments that impact equipment and other health care technology. They must also keep up with the changes in the health care delivery system. Some of the clinical engineers have become so involved in continuing education that they have actually changed their career and have become physicians. Gilchrist describes an academic program on the retraining of clinical engineering personnel in some of the developments in biomedical engineering.

Distance education has become the way many clinical engineering staff receive continuing education. This has partially been brought about due to the cost of travel and the changes in technology. Of course, distance education is not new. Correspondence courses have been a form of distance education that has been around for many, many years. For a few years, audio teleconferencing has been used by the American College of Clinical Engineering to provide quality continuing education programs for engineers, and has been well received by both presenters and participants. The presenters do not have to travel and can make a presentation from the office. At the same time, the participants can receive the training during their lunch hour or at some other time at their local medical center.

Another method of continuing education utilizing technology has been video conferencing, which initially only involved “talking heads,” but has become a more real educational experience where skills and techniques can be demonstrated. Video conferencing takes two modes. One is two-way video conferencing, either over high-speed phone lines or through a satellite broadcasting system where people make a presentation and participants can ask questions. A more common method is a satellite broadcast, which is a one-way communication, but participants can ask questions through phone lines, fax systems, or e-mail. Video conferencing is considerably more expensive than audio conferencing, but if something needs to be shown, this is a methodology that can be utilized very efficiently. Audio teleconferencing and video teleconferencing allow for presentations to be made anywhere in the world and allow clinical engineers access to presentations by international experts.

The Internet with the World Wide Web has also become a technology that can be used for college education or continuing education. This technology can be used on a very low level, where material is put on a site and downloaded similarly to a handout in a classroom. It can be made interactive with an instant session through chat rooms or various messenger services. The Internet provides a method that instructors can interact with and answer questions from students. The Internet and the World Wide Web have provided an opportunity for clinical engineering personnel anywhere in the world to receive instruction from international experts.

In addition to clinical engineers participating in various continuing education activities, they also are the source of continuing education with in-service training for the clinical engineering staff and health care delivery staff such as nurses and physicians. Clinical engineers will provide health care providers with information on the latest technology with regard to medical instrumentation. They may also provide the education on codes and standards that relate to the equipment at a facility. Clinical engineers are heavily involved in education and training both for their own professional development and for the professional development of the health care providers in the clinical setting.

Academic Programs in North America

Tim Baker

The Journal of Clinical Engineering
University Heights, OH

The Journal of Clinical Engineering surveyed 106 universities, colleges, and technical schools that offer biomedical instrumentation technology training. Fifty-five of these institutions offer associate's degrees and/or certificates in biomedical instrumentation. The remaining 51 institutions offer undergraduate, master's, medical, and/or doctoral degrees in clinical engineering or with a focus on bioinstrumentation. This article describes the trends reported by the staff at these programs regarding curriculum, staff size, and student numbers and quality.

Survey of Academic Institutions in the United States

The Journal of Clinical Engineering surveyed 106 universities, colleges, and technical schools that offer biomedical instrumentation technology training. See Appendix A for the list of questions asked. Appendices B and C provide complete lists of institutions that received surveys. There was a 15 percent response rate to the survey, which was mailed and/or e-mailed in July 2001. A complete list of institutions that received surveys can be found at the end of this article. Of the 51 graduate and undergraduate programs, 32 offer an undergraduate degree, 43 offer a master's degree (one offers an MD/MA), and 39 offer doctoral programs, including seven that offer MD/PhD degrees.

Bachelor's degree programs are available in 20 states, including Arizona, Massachusetts, New York, Pennsylvania, Ohio, North Carolina, Maryland, Wisconsin, Louisiana, Georgia, Illinois, Texas, Connecticut, Alabama, California, Iowa, Michigan, Virginia, Tennessee, and Missouri, as well as the District of Columbia. (See Figure 66-1.)

Master's programs are available in 22 states, including Arizona, Massachusetts, California, Ohio, Texas, South Carolina, New York, North Carolina, Georgia, Maryland, Wisconsin, Illinois, Indiana, Louisiana, Alabama, Connecticut, Iowa, Tennessee, Washington, Utah, Virginia, Missouri, and the District of Columbia. (See Figure 66-2.)

PhD degrees are offered by schools in 20 states, including Arizona, Ohio, Massachusetts, South Carolina, New York, Pennsylvania, North Carolina, Georgia, Illinois, Wisconsin, Maryland, Indiana, Texas, Louisiana, Alabama, California, Connecticut, Washington, Tennessee, Missouri, and the District of Columbia. (See Figure 66-3.)

Associate's degree programs and certificate programs in biomedical engineering technology (BMET) are offered by schools in slightly more than half the states, including Alabama, Arkansas, California, Connecticut, Delaware, Florida, Georgia, Illinois, Indiana, Massachusetts, Virginia, Washington, Wisconsin, Tennessee, Texas, South Carolina, South Dakota, Pennsylvania, Ohio, Oklahoma, Missouri, New Jersey, New York, North Carolina, Maryland, Michigan, and Minnesota—a total of only 28 states. (See Figure 66-4.) The Canadian provinces of Alberta, British Columbia, and Ontario boast institutions that offer AA/certificate BMET programs; however, they were not included in this survey.

Texas and Pennsylvania are the states with the most options for students looking to earn an associate's degree or certificate in biomedical equipment testing, maintenance, and repair; they offered four programs each at the time of the survey. However, Penn State, which offered clinical engineering at both its Wilkes-Barre and New Kensington campuses, discontinued the Wilkes-Barre program at the end of 2001 due to a lack of student interest.

Other AA/certificate programs recently discontinued include an associate's degree in biomedical engineering offered by Baker College in Flint, Michigan and an associate's degree program in biomedical equipment technology from the Northwest Technical College in Detroit Lakes, Minnesota.

States with three clinical engineering programs include Illinois and Washington. States with two programs include Alabama, California, Florida, Georgia, Indiana, Massachusetts, South Carolina, Ohio, Wisconsin, Tennessee, and North Carolina. States with one program include Arkansas, Connecticut, Delaware, Virginia, South Dakota, North Carolina, Oklahoma, New Jersey, Missouri, New York, Maryland, and Minnesota.

States that do not offer BMET AA/certificate schooling include Oregon, Nevada, Idaho, Montana, Utah, Arizona, New Mexico, Colorado, Wyoming, North Dakota, Nebraska, Kansas, Louisiana, Iowa, Louisiana, Mississippi, West Virginia, Maine, Vermont, New Hampshire, and Rhode Island.

Canadian schools that offer BMET AA/certificate programs include the Northern Alberta Institute of Technology in Edmonton Alberta, the British Columbia Institute of Technology in Burnaby, and Fanshawe College in London, Ontario.

Associate's Degree/Certificate Program Trends

Results from the survey reveal that information technology and management are not high priorities in the curriculum of most trade schools and associate's degree programs. This finding was particularly interesting given the growing importance of the microchip and networking in the day-to-day use of many devices used at the patient interface within hospitals and clinics. Many biomedical equipment technicians (BMETs) and clinical engineers (CEs) have expressed concern that their departments will eventually become divisions of hospital information technology (IT) departments unless BMETs and clinical engineers master these internet-age skills. However, US schools that train BMETs do not seem to be addressing the issue.

As seen in Figure 66-5, about half of the training for BMETs focuses on equipment repair and preventive maintenance. Thirty percent of the typical curriculum focuses on electrical engineering and electrical safety. Only 15 percent of the course of study focuses on computer science, including database management, LAN devices, and networking. About 10 percent is dedicated to human physiology and medical terminology.

One disturbing result of the survey is that the quality of incoming BMET students has declined. (See Figure 66-6.) About 70 percent of those who responded said that student quality had declined in the ten years from 1991 to 2001.

While this finding contains a degree of subjectivity, student enrollment does not. Half of the BMET training programs that responded said student enrollment declined from 1991 to 2001. Half reported that it has remained steady, or that it has slightly declined. Two-thirds of these respondents reported that they are worried about the future viability of their programs.

When asked if these educators are worried about the future of the industry, the answers were almost always indicative of the local environment, not national trends. Where there is strong hospital support and outreach to local BMET students, educators reported that they were not worried about the future employment prospects of their graduates. Educators in smaller towns or rural regions, where one might expect job opportunities to be scarce, seemed to be the most confident. Many of these programs reported having strong ties to local hospitals and good reputations for producing high-quality BMET graduates.

Most BMET training programs have three or fewer staff members. About 15 percent have six or more. (See Figure 66-7.)

The BMET student population reported by survey respondents ranged from two to 110. The average was 34 students, the mean was 56 students, and the median was 18 students. Seventy percent of the respondents reported having 20 students or fewer enrolled as of 2001. Twenty percent reported having more than 100 students. Thirty percent had fewer than 10 students.

Undergraduate and Graduate School Trends

Universities that offer undergraduate and graduate coursework in biomedical engineering reported that the interest in their programs is on the rise. Most reported a 20 to 50 percent increase in the student population from 1991 to 2001. Nearly all of these programs have staff sizes of fewer than 10 people. Only a few reported having a staff of more than 25 members. (See Figure 66-9.) Two-thirds of these universities reported that the quality of entering students is better today than it was in 1991. (See Figure 66-10.)

The focus of study at US undergraduate and graduate clinical engineering programs is equally split between electrical engineering and computer science (see Figure 66-8); the latter group includes computerized medical instrumentation, telemetry, web-enabled devices, database management, LAN devices, and general information technology. The University of North Carolina at Chapel Hill devotes nearly 70 percent of its curriculum to computer science.

Figure 66-1 Twenty states plus the District of Columbia offer bachelor's degree programs in Clinical Engineering.

Figure 66-2 Twenty-two states plus the District of Columbia offer Clinical Engineering master's degree programs.

Figure 66-3 Twenty states plus the District of Columbia offer Clinical Engineering PhD programs.

Figure 66-4 Twenty-eight states offer associate degree and/or certificate programs in Biomedical Equipment Technology.

Figure 66-5 Typical curriculum at associate's degree schools that responded to the survey.

As expected at this level of study, less than five percent of total instruction time is spent on electrical safety testing. None of the respondents from undergraduate and post-graduate schools reported teaching infection control.

The survey questionnaire failed to ask for student enrollment broken down by undergraduate and graduate student populations, so it is impossible to provide this information. Overall, graduate and undergraduate clinical engineering student populations ranged from 10 to 320. The average was 147 students, the mean was 165 students, and the median was 110 students. Sixty percent of the respondents reported having 100 or more students. Only 15 percent reported having 10 or fewer students as of 2001.

Why Programs Fail

In the last 18 months, several BMET associate's degree or certificate programs have been discontinued, primarily because of a lack of students. The deans and program directors at several schools expressed genuine concern about the future viability of their BMET training programs.

An interview with Albert Lozano, an assistant professor of engineering at the School of Engineering Technology and Commonwealth Engineering, Pennsylvania State University at Wilkes-Barre, provided some insight into why established BMET training programs with good reputations are discontinued. The Penn State Wilkes-Barre BMET program was discontinued in 2001 due to a sharp decline in student interest.

"Enrollment in the 2-year program continued to decrease over the last several years—two to three years—before we ended the associate's degree in Biomedical Equipment Technology program," Lozano said. "In fact, there were only two students in the last class. The interest on the part of the biomed kids just dropped."

Fortunately for the students of northeastern Pennsylvania, Penn State continues to offer associate's degrees in electrical engineering technology and telecommunications engineering technology as well as a baccalaureate degree in electrical engineering technology at Wilkes-Barre. "The interest in these has declined as well, but not to the extent of the biomedical associate degree," Lozano said.

The biomedical equipment technology program existed at Wilkes-Barre for more than 15 years and had been accredited by the Technology Accreditation Commission (TAC) of the Accreditation Board for Engineering and Technology (ABET) until it was discontinued. Penn State still offers the program at the New Kensington Campus, near Pittsburgh.

Figure 66-6 Response by associate's degree/certificate programs to the following question: "How would you describe the quality of incoming students compared with students ten years ago?"

Figure 66-8 Typical curriculum at US undergraduate and graduate clinical engineering programs.

Figure 66-7 Typical staff size at responding associate's degree/certificate programs.

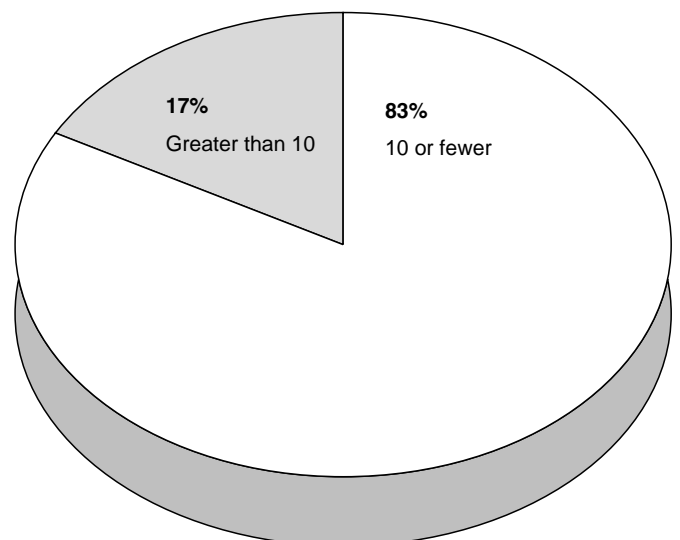

Figure 66-9 Typical staff size at U.S. undergraduate and graduate clinical engineering programs.

Lozano said he believes that several factors contributed to the demise of the Wilkes-Barre program. First, he said he thinks there is a stigma attached to all two-year degree programs that discourages students from pursuing them and parents from supporting them. Second, at the time the program ended, the economy was booming. "Students were finding it easy to make money without too much education," he said. Many students who were technically gifted found work in information technology. This leads to Lozano's third theorized reason: The lure of IT and computer engineering. That work is far more enticing to high-school graduates who are interested in technical careers, Lozano believes. Lastly, Lozano suspects that the curriculum at Penn State, where associate's degree graduates must take physics, extensive mathematics, English, and other humanities, hurt recruitment. "Students realized they could earn a degree in biomedical maintenance from a technical school without having all of this extra coursework and could still find good jobs. Of course, we feel that we produce a different, more global and competent kind of graduate, but students may feel they did not need the humanities and other courses."

Lozano also said that the low profile of the biomedical equipment profession also made recruiting young students difficult. Many potential students and their parents simply do not understand what a BMET does, which adds an extra hurdle to the recruitment process. "Society doesn't have a good understanding of what a biomedical professional does. It's an unknown profession," Lozano said.

Lozano also believes that there is an overall decrease in interest among US high-school graduates in technical subject matter, which hurts all areas of science. Programs such as the Wilkes-Barre BMET associate's degree, which were not wildly popular to begin with, are particularly impacted by this trend.

Based on his recruitment experience within high schools, Lozano has learned that many parents discourage their children from working toward a two-year degree, which is a problem with most associate's degree programs no matter what the topic. "Parents often ask if their child with a two-year degree will get a good job with a salary that is comparable to that of a graduate with a four-year electrical engineering degree." Parents

Figure 66-10 Ranking of student quality at US undergraduate and graduate Clinical Engineering programs compared to students ten years ago.

generally want their children to have four-year degrees, even though this is not necessary to thoroughly train qualified BMETs.

The termination of the Wilkes-Barre program has not gone unnoticed by local hospitals, Lozano said. There are approximately 15 hospitals in the Wilkes-Barre region and in nearby Binghamton, New York that relied on the program for new BMETs. Lozano said that 80 percent of his associate's degree graduates were placed at local hospitals. Support from the hospitals was strong. Many offered internships and donated equipment for training purposes. "Hospitals still often call saying 'we need more graduates'; we just have to say 'sorry, the program has ended'."

Lozano said student quality was not an issue, just student interest. In fact, the employers praised the quality of the graduates. Those who were eager to enter the biomedical field and work in hospitals were high-caliber students. "There were just too few of them," he said.

Lozano feels that the Wilkes-Barre program offered a curriculum that trained students for the realities of the modern BMET profession. The training focused less on component-level troubleshooting in favor of networking, risk management, safety, and technology integration. The program relied on biomedical professionals from local hospitals who worked on the program's curriculum committee. Based on the recommendations of these professionals, the program continued to revise the curriculum to fulfill the current demands of the profession.

Lozano is still in contact with many of his previous students, most of whom are happy in their chosen profession and are doing well. One student who graduated in the late 1990s began working at a New Jersey hospital at a salary of \$35,000 plus benefits includ-

ing an automobile. There are not many entry-level positions that offer such generous compensation, he added. Within about two and a half years, that student was making \$50,000 at the same hospital.

Specific Comments

"In the last five years, the school has made an effort to improve the program and work with area hospitals to provide up-to-date learning experiences," said one BMET program director. "The program has also worked to provide some educational materials on-line for students who are located throughout the country. Student interest is increasing as the school has put more effort into recruiting and publicity. Student quality is improving as admission requirements to the university have tightened over the last five years. Our program continues to thrive given the high demand for graduates and the on-line environment attracting a wider geographic population. Two years is only enough time (to train BMETs) to provide the basics. However, we find that employers would prefer to customize additional education opportunities as they see fit."

One professor at a BMET associate's degree program is not worried about the future of the profession. "We have steady enrollment, and there are always jobs to be found," he said. "There are not many other programs in the area, and we have good hospital support." Two years of training is enough for BMETs, especially "with comprehensive internships and continuing education from manufacturers. Our grads know how to keep learning."

On the same topic, a department chair of a BMET and radiology-technician program said, "For a general BMET program, two years (training) is more than enough. It's the quality and efficiency of the training program that counts, not so much the length."

One BMET instructor said that he is worried about the future of his program in particular, and the profession in general. "Starting salaries and working conditions are not attractive to today's students."

One director of an associate's degree program described the curriculum and goals of the program as follows: "The Biomedical Equipment Technology curriculum prepares individuals to install, operate, troubleshoot, and repair sophisticated devices and instrumentation used in the health care delivery system. Emphasis is placed on preventive and safety inspections to ensure that biomedical equipment meets local and national safety standards. Course work provides a strong foundation in mathematics, physics, electronics, anatomy and physiology, and troubleshooting techniques. People skills are very important, as well as the ability to communicate both in written and oral form. A biomedical equipment technician is a problem solver. Graduates should qualify for employment opportunities in hospitals, clinics, clinical laboratories, shared-service organizations and manufacturers' field service. With an AAS degree and two years experience, individuals should be able to become a certified biomedical equipment technician."

One staff member at an associate's degree program said, "I am very concerned about the program. One program in (our state) has already folded because of a lack of interest. Student quality is much worse than ten years ago. Students can't do algebra and can't write on a college level."

"Our biomedical electronics major teaches students how to repair, calibrate, and evaluate the performance of electro-mechanical equipment used in the medical fields," said one professor at an associate's degree program. "Students receive a strong background in electronics and the sciences, as well as training in various areas of biomedical equipment."

This individual is worried about the future. "Due to the reforms in health care, there is a negative perception to working in the health care field, and with the new areas of computer information systems and networking, there is difficulty in recruiting students into biomedical engineering technology." "With all of the changes in health care technology, two years is still sufficient time for the fundamental training that a BMET requires; then it becomes on-the-job training and specialized training after employment."

Appendix A: Survey Questions

1. Does your school offer a degree/certification?

- Certificate
- Biomedical equipment technician
- Radiology equipment specialist
- Clinical laboratory equipment specialists
- AA/AS degree
- Bachelor's of science (or arts) degree
- Master's degree
- PhD
- ScD

2. Please give the formal name of your program(s) and degree(s).

3. If yours is a certificate program, how many quarters of study are required?

4. How long has your program(s) existed?

5. Describe your curriculum.

6. How much of the curriculum focuses on (provide %):

- Hands-on maintenance and PM? (%)
- Medical terminology? (%)
- Management? (%)
- Infection control? (%)
- Electrical safety testing? (%)
- Electrical engineering? (%)
- Human physiology? (%)
- Computerized medical instrumentation? (%)
- Web-enabled medical devices? (%)
- Telemedicine? (%)
- Telemetry? (%)
- Database management? (%)
- Information technology? (%)
- Microsoft NT training? (%)
- Unix training? (%)
- Computer OS certification preparation? (%)
- LAN devices? (%)
- Computer languages, such as C++? (%) (If so, please list languages.)

7. State your name and title.

8. How many people are on your staff, and what is their training?
9. What is the student population today?
10. What was the student population ten years ago?
11. Is student interest declining?
12. Is student quality
 - the same as ten years ago?
 - better than ten years ago?
 - worse than ten years ago?
13. Are you concerned about the future viability of your program? (If so, please elaborate.)
14. With all of the changes in health care technology, are two years sufficient training for a BMET? (Please elaborate.)
15. Are you considering offering more specialty training? (Please elaborate.)
16. Do you require internships?
 - Yes
 - No

Appendix B: BMET Certificate and Associate's Degree Programs by State

<i>State</i>	<i>Institution</i>	<i>Degree</i>
Alabama	Jefferson State Community College	College associate's degree
	Northwest-Shoals Community College	Certificate in biomedical equipment technology
Arkansas	University of Arkansas for Medical Sciences	Associate's degree
California	Los Angeles Valley College	Two-year electronics technology certificate
	Santa Barbara City College	Associate's degree/certificate
	Napa Valley College	Associate's degree
Connecticut	Gateway Community College	Associate's degree
Delaware	Delaware Technical and Community College	Associate's degree
Florida	Broward Community College	Associate's degree
	Santa Fe Community College	Associate's degree
	Florida Community College at Jacksonville	Associate's degree
	Keiser College of Technology-Fort Lauderdale	Associate's degree
Georgia	Central Georgia Technical College	Certificate in biomedical electronics
	Chattahoochee Technical College	Associate's degree
Illinois	Richland Community College	Associate's degree in biomedical electronics
	South Suburban College	Associate's degree/certificate in biomedical electronics technology
Indiana	Indiana University-Purdue University at Indianapolis	Associate's degree
Kentucky	Madisonville Community College	Associate's degree
Maine	Southern Maine Technical College	Associate's degree
Massachusetts	Franklin Institute of Boston	Medical electronics
	Quinsigamond Community College	Engineering program
	Bunker Hill Community College	Associate's degree
	Springfield Technical Community College	Associate's degree
Maryland	Howard Community College	Associate's degree
Michigan	Baker College	Associate's degree (discontinued)
	Schoolcraft College	Associate's degree
Minnesota	Northwest Technical College	Associate's degree (discontinued)
Missouri	St. Louis Community College-Florissant Valley	Associate's degree
New Jersey	Thomas Edison State College	Associate's degree
New York	Erie Community College	Associate's degree
North Carolina	Stanley Community College	Associate's degree
	Caldwell Community College and Technical Institute	Associate's degree
Ohio	Cincinnati State Technical and Community College	Associate's degree
	Owens Community College	Associate's degree
Oklahoma	Tulsa Community College	Associate's degree in (electronics, with biomedical equipment technology option)
Pennsylvania	Penn State, Wilkes-Barre	Associate's degree (discontinued)
	Penn State, New Kensington	Associate's degree
	Community College of Philadelphia	Associate's degree
	Johnson Technical Institute	Associate's degree
South Carolina	Greenville Technical College	Certificate in biomedical equipment Technology (after completion of an AS in electronics)
	York Technical College	Certificate program
South Dakota	Southeast Technical Institute	Certificate program
Tennessee	Southwest Tennessee Community College	Associate's degree
Texas	Grayson County College	Certificate program
	Texas State Technical College-Harlingen	Associate's degree
	St. Philip's College	Associate's degree
	College-Waco	Associate's degree
Virginia	ECPI College of Technology	Associate's degree
Washington	North Seattle Community College	Associate's degree
	Spokane Community College	Associate's degree
Wisconsin	Western Wisconsin Technical College	Associate's degree
	Milwaukee Area Technical College	Associate's degree
Alberta, Canada	Northern Alberta Institute of Technology	Two-year diploma
British Columbia	British Columbia Institute of Technology	Two-year diploma
Ontario	Fanshawe College	One-year post-graduate diploma

Appendix C: Undergraduate and Graduate Programs by State

<i>State</i>	<i>Institution</i>	<i>Degree</i>
Alabama	University of Alabama	MS, PhD
Arizona	Arizona State University	BS, MS, and PhD
	University of Arizona	MS and PhD
California	California State University-Sacramento	MS
	University of California at Berkeley	PhD
	University of California at San Diego	BS, BA, MS, PhD, MD/MS, and MD/PhD
	University of Southern California	BS, MS, and PhD
Connecticut	Trinity College	BS
	University of Connecticut	MS and PhD
	University of Hartford	BS
Georgia	Georgia Tech	MS and PhD
	Mercer University	BS and MS
Illinois	Northwestern University	BS, MS, and PhD
	University of Illinois-Chicago	BS, MS, and PhD
	University of Illinois-Urbana/Champaign	BS, MS, PhD
	Southern Illinois University-Carbondale	BS in electronic management
Indiana	Purdue University	MS and PhD
	Indiana University-Purdue University at Indianapolis	BS
	Indiana State University	BS
Iowa	University of Iowa	BS, MS, and PhD
Louisiana	Tulane University	BS, MS, and PhD
Maryland	Johns Hopkins University	BS, MS, and PhD
Massachusetts	Boston University	BS, MS, PhD, and PhD/MD
	Worcester Polytechnic Institute	BS, MS, and PhD
Michigan	University of Michigan	BS and MS
Missouri	Washington University	BS, MS, and PhD
New Jersey	Thomas Edison State College	BS
New York	Columbia University	BS, MS, and PhD
	Cornell University	BS, MS, and PhD
	Rensselaer Polytechnic Institute	BS, MS, and PhD
North Carolina	Duke University	BS, MS, and PhD
	University of North Carolina at Chapel Hill	BS, MS, PhD, and PhD/MD
Ohio	Case Western Reserve University	BS, MS, PhD, and PhD/MD
	Ohio State University	MS, PhD, and MD/PhD
	University of Akron	BS, MS, and PhD
	Wright State University	BS and MS
Pennsylvania	Carnegie Mellon University	BS, MS, and PhD
	Drexel University	MS and PhD
	University of Pennsylvania	BS, MS, and PhD
	University of Pittsburgh	BS, MS, PhD, and MD/PhD
South Carolina	Clemson University	MS and PhD
Tennessee	Vanderbilt University	BS, MS, and PhD
	East Tennessee State University	BS
Texas	Rice University	MS and PhD
	University of Texas	MS and PhD
Utah	University of Utah	MS and PhD
Virginia	University of Virginia	BS/ME, MS, and PhD
	Virginia Polytechnic Institute	BS
Washington	Walla Walla College	BS
	University of Washington	MS, PhD, and MD/PhD
Wisconsin	Marquette University	BS, MS, and PhD

67

Clinical Engineering Education in Germany

Vera Dammann

Department of Hospital and Medical Engineering,
Environmental, and Biotechnology
University of Applied Sciences Giessen-Friedberg
Giessen, Germany

A member of the technical staff in a clinical engineering department in Germany has a formal technical education as a skilled craftsman, with or without specialization or additional higher qualification as "Meister," as a technician, or as an engineer with a university degree. All formal education is controlled by the government with regard to level of quality, duration, and final certificate. Education, entry requirements, and final examination with certificate at every level are regulated by law. Traditionally, universities issue the diploma in engineering after four or five years of study. There is no advanced degree except the doctorate. Since the late 1990s, there has been a trend at universities towards the bachelor/master system.

Most clinical engineers have a university diploma, usually from a university of applied sciences.

German System of Technical Education

Qualified Craftsman Level

Entrance qualification for the three- or three-and-half-year vocational training is a qualified school-leaving certificate of 10 years. The law states that young persons up to 18 years of age may be trained only in a recognized training occupation. Attendance at vocational schools is compulsory (up to 12 hours per week). The setup of the vocational schools is largely standardized. The on-the-job training takes place in a hospital or related enterprise and is characterized by its systematic and casuistic nature, as defined by training regulations (the federal syllabus for in-plant training) and the presence of the trainer and Meister¹ specialized in training, to guide the apprentice. Public vocational schools do not charge study fees; the apprentice gets a small salary from the enterprise.

There is no formal vocational training for a medical technology craftsman. Craftsmen working in the clinical engineering field go through an apprenticeship in electronics or mechanics and obtain experience through several years of on-the-job training in a maintenance workshop and/or by attending special seminars offered by institutions of continuing education or by the manufacturers of medical devices. These seminars qualify the apprentice for single, usually rather simple, tasks; e.g., maintenance of a specific type of infusion pump.

The head of an electronics or mechanics workshop in a clinical engineering department is usually an experienced master craftsman, i.e., "Meister."¹ The Meister certificate is also necessary to run a private workshop offering maintenance service in Germany. This regulation is effective in all commercial fields.

Technician Level

An experienced biomedical engineering technician (BMET) in Germany is called "medical technician" and is allowed to carry out all maintenance, instruction, and documentation tasks in clinical engineering. The medical technician is aware of the legal requirements concerning his or her work, and at any time must be able to demonstrate the way in which necessary special knowledge for dedicated maintenance tasks was gained.

Ten technical colleges/technician schools offer medical technician courses for a fee, and the entrance requirement is relevant vocational training. A course takes 2400 to 2900 contact hours (i.e., two years full-time or four years part-time) and ends with an examination acknowledged by the state.

In contrast to the designation "engineer", (Ingenieur), the general term "technician" is not protected by law in Germany. The title "certified technician" (staatlich geprüfter Techniker), however, is reserved for technicians who passed the exam at a certified technical school.

University Level

Clinical engineers hold a university degree, the diploma in engineering. There are two types of universities offering courses in (bio)medical engineering/clinical engineering: the traditional-style university, "Universität," and the university of applied sciences (UAS), "Fachhochschule (FH)." The diplomas of the two university types are equivalent under the law.

Clinical engineering is considered an applied science, and is taught in an interdisciplinary program at UASs based on physics, electronics, or precision engineering. All curricula comprise mathematics, physics, chemistry, data processing, electrical engineering, electronics, material sciences, mechanical engineering, human biology (e.g., physiology), physiological measurement, imaging, quality assurance, and safety. Most of the subjects are obligatory. Subjects are taught for up to half a semester. The amount of classical engineering sciences depends on the basic specialization (see Tables 67-2 and 67-3) of the biomedical engineering (BME) department. For example, curricula based on mechanics could include computer-aided design. All new revisions of the curricula show an increase in so-called nontechnical subjects like economics, quality assurance, management, law, and foreign languages.

Traditional universities offer biomedical engineering courses for course specialization within electrical or mechanical engineering or physics in the third or fourth year of study.

All graduates can work as clinical engineers directly after graduation, without any additional certificate. Since every university and every course of study must be accredited by the government (ministries of science and education), the quality is defined and the level of examination is high. It is up to the employer to decide whether to hire a "greenhorn" or an experienced engineer.

Traditional System

As all the German institutions are public and lie within the formal and financial responsibility of the respective state governments, the framework of all studies is similar to the following:

- Admission requirements: At least 12 years of elementary and secondary school (comparable to A-level) plus practical workshop experience of two to six months
- Six semesters (at universities of applied sciences) or eight semesters (at traditional universities) of full studies (25 to 30 lesson hours per week, including exercises and lab work)
- One or two half-years of internship in industry or hospital with supervised project work at universities of applied sciences.
- An individual final examination project (three to six months in a university laboratory, in research and development, or at a hospital under the supervision of a professional) with a thesis at the end
- A degree in engineering at graduation: "Dipl.-Ing." The UAS adds the abbreviation *FH*: "Dipl.-Ing. (FH)." Law protects the designation "Ingenieur."
- The diploma of a UAS is at a level between bachelor's and master's degrees, while the diploma of a traditional university is master's level.
- Only the traditional universities can offer a doctorate, but graduates of both traditional institutions or UASs may enter a doctorate program. Graduates of a UAS, however, may be required to pass an additional year of advanced theoretical studies.
- Students are not charged a study fee. This is a form of scholarship that the German government grants to every enrolled student, including students from foreign countries.

Development of New Structures

Since the late 1990s, most German universities have redesigned existing courses of study to create modularized courses, leading consecutively to the bachelor's, the master's, and the doctoral degree. In addition to the approval by the respective ministry, such new courses should be accredited by an independent agency. The modules in the new courses

¹ The qualification "Meister" requires a successfully accomplished vocational training plus some years of experience on the job and the attendance of a "Meister course" of about one year. The Meister course and final exam cost about 20,000 Deutschmarks (DM). The certificate is issued by the respective chamber or guild.

are credited by the European Credit Transfer System (ECTS). The number of credit points for a module depends on the amount of work the student invests. A full year of studies equals 60 ECTS points. The ECTS² was created in order to acknowledge exams passed at another university within the European Union.

Harmonization of university courses and degrees in Europe is now carried out according to the “declaration of Bologna 1999.”³

Promoted by a conference of all university presidents, financially supported by the federal ministry of education and science, and assisted by the German Academic Exchange Service (DAAD),⁴ several dozen international courses of study at the bachelor’s and master’s level have been created. These new courses offer first-year lessons in a foreign language (mainly English) and integrate a compulsory student exchange with an institution abroad. The “International Studies in Clinical Engineering” program at the UAS in Giessen⁵ is part of this promotional program. It leads to the bachelor’s degree after three years and the bachelor’s degree with honors after four years.

Continuous Education in Clinical Engineering

In addition to the degree courses at universities and product-related courses offered by manufacturers, many universities and private institutions offer seminars and workshops in the following areas:

- Legal aspects of medical devices for manufacturers, distributors, owners, or maintainers
- Maintenance, safety tests, or calibration of special kinds of medical devices
- Health care technology management
- Quality assurance, quality management, and auditing

Regional groups of clinical engineers organize meetings with experts for special discussions and for the presentation of new technology. Clinical engineers attend medical congresses, including the annual congress of clinical engineers held by the Fachverband Biomedizinische Technik e.V. in Würzburg.⁶ The MEDICA,⁷ the world’s greatest exhibition of medical devices, is another forum for seminars and workshops that takes place each November in Duesseldorf.

Lists of Technician Schools and Universities Offering Courses in Clinical Engineering

Table 67-1 lists certified technician schools. Table lists 67-2 UASs. Table 67-3 lists traditional universities.

Table 67-2 Universities of Applied Sciences (for actual URLs of the institutions please refer to www.fbmt.de → Information → Studium)

City	Address	Course, Degree	Basing on
Berlin	Technische Fachhochschule Berlin Luxemburger Str. 10 D-13353 Berlin	“Medizinisch-Physikalische Technik” Diploma	physics
Bremerhaven	Hochschule Bremerhaven An der Karstadt 8 D-2568 Bremerhaven	“Medizintechnik” Diploma	physics
Gelsenkirchen	Fachhochschule Gelsenkirchen, Neideburger Str. 43, D-45897 Gelsenkirchen	Mikrotechnik und Medizintechnik” specialising in “Gesundheitstechnik” Diploma	physics
Giessen-Friedberg	Fachhochschule Gießen-Friedberg, Bereich Gießen Wiesenstr. 14, D-35390 Gießen	“Medizintechnik” Diploma (planned: bachelor’s and master’s) or International Studies Clinical Engineering” Bachelor or “Computer Science in Medicine” Diploma (planned: bachelor’s and master’s)	physics
Hamburg	Fachhochschule Hamburg Lohbrügger Kirchstr. 65, D-21033 Hamburg 80	“Medizintechnik” Diploma (planned: bachelor’s and master’s)	physics
Jena	Fachhochschule Jena, Tatzendpromenade 1b, D-07745 Jena	“Biomedizinische Technik” Diploma	physics
Jülich	Fachhochschule Aachen Abteilung Jülich Ginsterweg 1 D-52428 Jülich	“Physikalische Technik” specialising in “Biomedizinische Technik” Diploma	physics
Köthen	Fachhochschule Anhalt in Köthen Bernburger Str. 52-57 D-06366 Köthen	“Elektrotechnik” specialising in “Biomedizinische Technik” Diploma	electrical engineering
Lübeck	Fachhochschule Lübeck Stephensonstr. 3 D-23562 Lübeck	“Medizintechnik” Diploma	physics
Mittweida	Fachhochschule Mittweida Technikumsplatz 17 D-09648 Mittweida	“Physikalische Technik” specialising in “Medizinische Technik” Diploma	physics
München	Fachhochschule München Lothstr. 34 D-80335 München	“Feinwerk- und Mikrotechnik” specialising in “Medizintechnik” Diploma	precision mechanics
Münster	Fachhochschule Münster, Abteilung Steinfurt Stegerwaldstr. 39 D-48565 Steinfurt	“Physikalische Technik” specialising in “Medizintechnik” Diploma	physics
Remagen	Fachhochschule Koblenz/RheinAhrCampus in Remagen Südallee 2 D-53424 Remagen	“Medizintechnik und sportmedizinische Technik” Diploma	
Stralsund	Fachhochschule Stralsund Zur Schwedenschanze 15 D-18435 Stralsund	“Medizininformatik und Biomedizinische Technik” Diploma	electrical engineering and computer science
Villingen-Schwenningen	Fachhochschule Furtwangen in Villingen-Schwenningen, Jakob-Kienzle-Str. 17 D-78054 Villingen-Schwenningen	“Medical Engineering” Diploma	mechanical engineering
Ulm	Fachhochschule Ulm, Albert-Einstein-Allee 55 D-89081 Ulm	“Medizintechnik” Diploma	precision mechanics
Wilhelmshaven	Fachhochschule Wilhelmshaven, Friedrich-Paffrath-Str. 101 D-26389 Wilhelmshaven	“Medizintechnik” Diploma or Biomedical Engineering Diploma	precision mechanics
Zwickau	Fachhochschule Zwickau Dr.-Friedrichsring 2A D-08056 Zwickau	“Physikalische Technik” specialising in “Biomedizinische Technik” Diploma	physics

Clinical Engineering Internship

Izabella A. Gieras

Clinical Engineer, Clinical Engineering and Technology Management Department,
Beaumont Services Company, LLC
Royal Oak, MI

Frank R. Painter

Biomedical Engineering Graduate Program, University of Connecticut
Trumbull, CT

Education is a fountain of knowledge. It is through this knowledge that one gains experience and the indispensable preparation to go forth in life. People choose to pursue educational disciplines including arts, law, medicine, engineering, and business. However, some brave souls choose to pursue the magical and mysterious world of biomedical engineering. Biomedical engineering concentrates on the use of engineering principles and practices to search for new knowledge of life processes. The field includes the search for applications to cure and control diseases and ways to provide life support to humans and animals (Bronzino, 1995).

Clinical engineering is the newest and most diverse subspecialty of biomedical engineering. It combines the application of engineering and managerial skills with health care technology for ultimate support and advancement in patient care. Clinical engineering encompasses such areas as biochemical engineering, bioinstrumentation, biomaterials, biomechanics, biomedical imaging, ergonomics, and neurobiology (Bauld, 1991).

The University of Connecticut (UCONN) at Storrs, Connecticut is one of several academic institutions that have instituted programs in clinical engineering. UCONN offers an excellent graduate degree in biomedical engineering with a clinical engineering internship. Students complete their master's degree while they work in a hospital environment acquiring skills and an understanding of clinical engineering in action. This chapter describes the origins, present curriculum, hospital affiliations, and typical activities of the UCONN clinical engineering internship program.

Internship History

The clinical engineering internship was established in the greater Hartford area in 1974 and moved its academic affiliation to the University of Connecticut in 1997. Students who pursue this program earn a Plan A Master of Science (MS) in biomedical engineering that requires a minimum of 24 credit hours of course work and a thesis. A Bachelor of Science (BS) degree in either engineering, physical sciences, or mathematics is a prerequisite for admission to the biomedical engineering program at UCONN. (See www.bme.uconn.edu).

University of Connecticut MS Curriculum

The MS in biomedical engineering at UCONN consists of a total of eight graduate courses (3 credits each), the thesis project (9 credits), and intern experience (6 credits). There are three courses that form the foundations for the degree and for the specialized clinical engineering internship program associated with it. The following courses are required for all clinical engineering interns:

- Physiological Systems I
- Clinical Engineering Fundamentals
- Clinical Instrumentation Systems

The rest of the curriculum consists of biomedical engineering graduate courses, which should be from engineering disciplines related to the intern's background, interests and future career plans. The typical student's workload consists of two classes per semester. Students spend their summer vacation researching master's thesis projects. During the two academic years of this program, students work at affiliated hospitals while taking courses and working on their theses.

Internship Affiliations

The UCONN clinical engineering internship program relies upon local hospitals with which it has formal affiliations. Those in Connecticut include Hartford Hospital, the University of Connecticut Medical Center, Yale/New Haven Hospital, West Haven VA Medical Center, and St. Francis Hospital. The program is also associated with Bay State Medical Center in Springfield, Massachusetts. Students are required to spend approximately 20 hours per week working in the hospital. Each hospital is unique in terms of the research and projects available to the interns and the ways in which clinical engineering is practiced. For example, the Hartford Hospital internship primarily provides technical support and consultation to all engineering and maintenance departments throughout the hospital (Rosow, 2002). Students have the opportunity to get involved in repair and maintenance of clinical and medical equipment while being exposed to numerous projects in research and development applications using programming software such as LabVIEW and BioBench (see Chapter 100). The biomedical engineering department at Hartford Hospital provides an enriching experience in terms of its versatile engineering and clinical projects, such as the machine vision project (see Chapter 92).

The University of Connecticut Medical Center's program supports all medical equipment, including clinical laboratories and radiology. The clinical engineering department provides students with skills in electronics, reading and comprehension of service and maintenance manuals, repairs, inspections, and special departmental projects. Due to its affiliation with the University of Connecticut Medical School, the hospital provides a fertile environment for student research. Thesis projects often stem from such research opportunities.

The Yale/New Haven Hospital offers exposure to a wide range of hospital specialties, including clinical laboratories, diagnostic imaging, and hemodialysis. Interns work on repairs, inspections, and clinical education program development.

The West Haven Veterans Administration (VA) Hospital is closely affiliated with the Newington, CT VA Hospital and is part of the Veterans Service Integrated Network 1 (VISN 1), VA New England Health care System. VISN1 is perhaps the largest health care network in New England. The VA New England Health care System is comprised of eight medical centers and 37 community-based outpatient clinics throughout the six New England states. Students are exposed to a variety of technology projects related to the requirements of the VA patient population. Students can become involved with the medical research activity that the Yale School of Medicine conducts at the West Haven VA.

St. Francis Hospital, in downtown Hartford, provides the student with exposure to a well-organized clinical engineering department with a focus on the practical aspects of technology management, a wide variety of current medical equipment, and a progressive clinical environment.

The Bay State Health System possesses modern test equipment and computer facilities and supports all hospital medical equipment. Interns are exposed to report preparations, oral presentations, asset management, database management, and medical device inspections.

Undoubtedly, this clinical engineering internship program offers indispensable, in-depth clinical and engineering opportunities through exposure to the hospital environment and the different academic courses offered. The two years that students spend in their respective hospitals provide them with excellent opportunities to pursue their personal interests while learning from numerous projects offered by each hospital.

First Year of the Internship

The clinical engineering internship program is structured in such a way that in the first year, clinical engineering interns dedicate their time to rigorous clinical rotations through-

out the hospital and participate in various projects undertaken at their respective hospitals. These rotations may include areas such as:

- Clinical engineering
- Respiratory therapy
- Operating room
- Physical therapy
- Anesthesiology
- Lab medicine/pathology
- Emergency room
- Diagnostic imaging
- ICU, adult and neonatal
- Nuclear medicine
- OB/GYN and labor & delivery
- Radiation oncology

Depending on individual interests, these rotations can vary from two weeks to one month. Interns are encouraged to interact with all clinical and medical personnel, and to learn not only the function of the equipment used in each area, but also the overall operation of each department through which they rotate.

In the first year, interns search for their potential master's thesis projects and subsequently start the necessary background research. Some responsibilities of the intern during the first year may include the following:

- Assisting in the equipment management program by performing corrective maintenance and preventive maintenance on specific medical equipment
- Learning and becoming proficient in the use of the equipment management software that is used in running the department
- Performing incoming inspections on new equipment
- Performing electrical safety testing and medical gas outlet testing
- Providing in-service training for medical equipment users
- Preparing technology assessment studies and product comparisons
- Providing administrative support to the director of clinical engineering with budgeting and Joint Commission on Accreditation of Healthcare Organizations (JCAHO) recommendations.

Second Year of the Internship

The second year of the internship program is dedicated to completing a clinical engineering-oriented thesis project. Depending on the hospital, the intern may continue to have various departmental responsibilities, using the remaining internship time on thesis project research. Students working on complex engineering and clinical projects gain valuable knowledge to enhance their clinical and engineering expertise. The overall success of this program is based on the following criteria (Gieras, 2000):

- Application of engineering techniques to patient care and hospital-based research
- Completion of diverse clinical rotations in different departments of the hospital
- Interaction with hospital personnel, including administrators, nurses, technicians, and medical staff

Professional Organization Involvement

During the clinical engineering internship, students become involved in a variety of societies, such as the American College of Clinical Engineering (ACCE) (see Chapter 130), the Association for the Advancement of Medical Instrumentation (AAMI), the American Society for Health care Engineering (ASHE), the New England Society of Clinical Engineering (NESCE) (see Chapter 131), and the Institute of Electrical and Electronics Engineering/Engineering in Medicine and Biology Society (IEEE/EMBS). Students are also encouraged to attend conferences, symposia, seminars, and workshops. The annual conference and exhibition of AAMI provides multidisciplinary programs that enrich the

attendees' knowledge and understanding of the development, management, and use of medical instrumentation and related medical technologies. (See www.aami.org.)

ACCE (see www.accenet.org) sponsors a wide range of educational programs, including a teleconference series (see Chapter 72), an annual symposium (Cohen, 2002), and Advanced Clinical Engineering Workshops (ACEW) in the United States (Dyro, 1999) and worldwide (see Chapters 70 and 71). ACCE members constitute the majority of speakers on clinical engineering at annual and regional conferences held by ASHE, AAMI, and IEEE. The workshops (ACEWs) provide an opportunity to learn from other clinical engineers about different aspects of clinical engineering, such as evaluation and acquisition of medical devices and systems, technology management, medical equipment inspections, medical device research activities, and medical device incident investigations.

NESCE cosponsors the annual Northeastern Biomedical Engineering Symposium, which provides a forum for interaction with other clinical engineering professionals and an opportunity to enhance technical skills and knowledge through numerous lectures, seminars, and courses (Francoeur, 2002). A large exhibit area offers an opportunity to inspect the latest medical device technologies and clinical engineering support tools.

Clinical engineering interns can also attend the annual IEEE EMBS Northeast Bioengineering conference, held at various universities throughout New England. This provides an excellent opportunity for all second-year interns to present papers about their thesis projects and to learn about research undertaken by their peers.

Students are also encouraged to become involved in local societies, such as the UCONN IEEE BMES/EMBS Society, where some hold positions as the society's president, vice-president, treasurer, and secretary. Students organize guest speakers, field trips, and social events in order to sustain the biomedical engineering tradition at UCONN. Participation in local societies is one way to maintain contact with peers and achieve professional advancement (see Chapter 132).

Life After Internship

The clinical engineering internship program endows students with excellent skills and knowledge. This leads to further academic studies, research activities, or professional work. Graduates from this program have been successful in taking the following paths:

- Clinical engineering departments of hospitals
- Clinical engineering departments of independent service organizations
- Medical device companies
- Medical schools
- PhD Programs
- Research
- Other academic disciplines related to biomedical engineering

Many graduates accept positions as clinical engineers or directors of clinical engineering departments. Some choose paths that take them into industry, working for companies like Phillips Medical, Zoll, and Baxter. Other students, driven by a passion for research and the search for further knowledge, choose academia. In summary, the UCONN clinical engineering internship program prepares students for career challenges in life.

Biomedical Engineering Technology Program

Bruce J. Morgan
Clinical Engineering Consultant
Riverside, CA

Developing a biomedical engineering technology curriculum is fraught with problems and compromises. This chapter examines the successful program at the State University of New York College of Technology at Farmingdale to see how one college dealt with the problems. The program was designed to be a two-year terminal program. That is, the majority of the graduates are expected to go directly to work in the health care field as biomedical equipment technicians (BMETs), although a small percentage continue with full-time education. As such, the program emphasized the specific skills the graduates would need to work in hospitals.

Overview

The electrical engineering technology courses concentrate on basic electrical theory and its relation to analog and digital systems. The lecture courses are analytical and problem-oriented to foster logical thinking and an understanding of the relations between various topics.

The electrical technology laboratory courses reemphasize the aspects learned in basic theory classes and show the theoretical principles applied to actual circuits. The laboratories are equipped with modern test equipment. All the EET courses have associated laboratory experiments, on which students work individually or in pairs. The biomedical technology laboratories are an integral part of the lecture courses and stress the development of analytical, mechanical, and inspection skills, which are essential in the industrial setting. The laboratories also provide an application of the material learned in lecture.

The biomedical engineering technology courses concentrate on the fundamentals of biomedical equipment technology, emphasizing safety concepts, operation of the health care system, and the application of technology to clinical problems. In order to keep the student current in the years following graduation, the program stresses the development of the individual's initiative and ability to learn independently.

There is a four-semester limit for an associate's degree, including several college requirements, such as two semesters of English and two social sciences courses. Also, it is the college's policy to have all degree courses accredited by the appropriate agency. The curriculum is based on the electrical engineering technology (EET) program due to the heavy emphasis on electronics in medical equipment.

Curriculum

Please note that one semester hour of credit consists of one hour of lecture or two to four hours of lab study per week for a fifteen-week semester.

Course Descriptions

BIO 165—Basics of Human Function

This course surveys the major physiological and morphological relationships of the human body's organ systems. The course emphasizes the integrative pathways and regulatory processes that reflect holistic concepts.

BME 202—Medical Instrumentation I

An introduction to the principles of operation and the clinical applications of medical instrumentation. Emphasis is placed on the electronic principles used in health devices, including amplifiers, signal conditioning, and power supplies. The course examines the integration of physics, chemistry, and electronics in medical devices, as well as hospital organization and the legal aspects of medical devices. Laboratory work includes experiments in electronics, medical equipment operation, preventive maintenance, and repair.

PHY 131 College Physics I	3	2	4
Social Science Elective	3	0	3
	12	11	17

BME 203—Medical Instrumentation II

A continuation of Medical Instrumentation II. Emphasis is placed on the operation of more sophisticated medical devices and systems, particularly those that are computer- or microprocessor-based. Laboratory work includes inspection and repair procedures for various types of equipment similar to that commonly found in operating rooms, intensive care units, clinical laboratories, and various clinical diagnostic units.

BME 254—Electronic Health Care Systems (BMET Clinical Internship)

Application of the principles learned in BME 202 and BME 203. Students work in a local hospital under the direct supervision of an experienced BMET or clinical engineer (Hines and Dyro, 1990). Emphasis is on the application of principles learned in lecture and laboratory to actual clinical situations.

CHM 140—Introduction to General Chemistry, Organic Chemistry, and Biochemistry

A one-semester course with laboratory work designed primarily for dental hygiene students and biomedical engineering students. Basic principles of general chemistry, organic chemistry, and biochemistry are presented with emphasis on their applications to health science. Topics include measurement, states of matter, bonding theory, solutions, acids,

buffers, and pH, and the structure and function of carbohydrates, lipids, sterols, amino acids, and proteins, as well as a molecular approach to enzymatic action, digestion, metabolism, and nutrition.

EET 101–Electric Circuits I

A basic course in direct current circuit theory, including Ohm's law, Kirchoff's law, analysis of series, parallel and combination circuits, mesh analysis, nodal analysis, superposition, Thevenin's, Norton's, and maximum power transfer theorems. Course work also includes study of electric fields and capacitance, magnetic fields and inductance, and analysis of R-C and R-L networks. The laboratory work is coordinated to support the theory course.

EET 102–Basic Instrumentation

The objective of this course is to familiarize the student with commonly adopted techniques and procedures of electronic instrumentation in an industrial setting. The curriculum includes measurement of current, voltage, power, frequency, and time using electronic instruments. The course also covers principles of transducers to extend instrument ranges and conversion of physical quantities to electrical signals.

EET 103–Electric Circuits II

This is the second of a two-course sequence to provide the background needed to analyze electric networks. Topics covered in this course include sinusoidal waveforms and nonsinusoidal waveforms. Also discussed are Fourier series and harmonics, the phasor representation of sinusoidal signals, steady-state conditions, series and parallel resonance, average power calculation, simple passive filters, frequency response (dB magnitude and phase) and its relations to the step response of simple RC, RL, and RLC networks, transformer principles, and types of transformers.

EET 107–Basic Electronics

The fundamentals of semiconductor diodes, bipolar junction transistors, and field effect transistors are discussed. The course analyzes basic diode, circuits, rectifiers, RC filters, zener diodes, and elementary zener regulated power supply, and describes three terminal IC regulators. Small signal single-stage bipolar and field-effect transistor amplifiers are analyzed in terms of voltage, current and power gains, and input and output impedance at midband frequencies. In addition, ideal operational amplifiers are discussed and analyzed in noninverting, summing, and difference amplifier configurations at midband. The laboratory portion of the course requires abridged and formal laboratory reports.

EET 108–Computer Applications I

An introduction to the application of computers in electrical technology. Topics covered are C programming as applied to electric network analysis and program control of electronic instrumentation using the standard IEEE-488 bus. Controlled instruments include switchers, power supplies, and multimeters.

EET 109–Computer Applications II

A continuation of EET 108, Computer Applications I. Topics covered include advanced programming in C, further use of the IEEE-488 bus, programmable instrumentation to perform automated testing of both electronic devices and networks, and the use of software for the analysis of electric networks.

EET 233–Digital Electronics

Analysis and design of combinational and sequential logic circuits. The curriculum addresses number systems, coding, Boolean algebra, Karnaugh map minimization technique, cod converters, SSI and MSI circuits, flip-flops, counters and shift registers, integrated circuit families, multiplexers, semiconductor memories, and D/A and A/D converters.

EET 251–Microprocessors

This course covers fundamental microprocessor concepts including theory of operation, circuitry, programming, signals, timings, and I/O interfacing, with laboratory work on microprocessor trainers. The student is required to interface input and output devices to the microprocessor and to quantify the associated hardware/software trade-offs.

EGL 101–Composition: Rhetoric

This expository writing course emphasizes the use of acceptable patterns of English and the application of rhetorical principles and research. Students will gain experience in the writing process, including revision. A research paper is required, with assignments in library research, note taking, outlining, and incorporation of sources into a final draft.

EGL 102–Composition: Literature

An introduction to plays, poetry, short stories, novels, and essays. Papers are written on forms, techniques, and themes of literature.

MTH 129–Technical Math A

This is a pre-calculus course with applications from various disciplines including technology, science, and business. Topics include families of functions, mechanics of functions, exponential and logarithmic functions, trigonometric functions, and complex numbers. The emphasis is on application and problem solving, and students must have a graphing calculator.

MTH 130–Technical Calculus A

This is a calculus course for those not majoring in mathematics, engineering science, or computer science. Topics include the derivative and differentiation of algebraic, trigonometric, exponential, and logarithmic functions, and applications of the derivative and the definite integral. Applications are taken from technology, science, and business. Problem-solving is stressed, and a graphing calculator is required.

PHY 131–College Physics I

This course integrates the theory and laboratory work of a general college physics course without calculus. Topics include fundamental concepts of units, vectors, equilibrium, velocity, and acceleration in linear and rotational motion, as well as force, energy, momentum, fluids at rest and in motion, and oscillatory motion. Students complete laboratory problems, experiments, and reports associated with the topics studied.

Biomedical Engineering Courses

All of the clinical engineering content is contained in the three biomedical engineering courses, BME202, BME203, and BME254. The courses are designed to give the students all the skills necessary to function in a hospital setting with a minimum of supervision. The curricula allow students to use available resources to fill in gaps in their knowledge.

The lecture courses, BME202 and BME203, given in the third and fourth semesters, respectively, contain some electrical engineering technology topics that are not covered in other courses. These topics include subjects from large signal amplifiers, integrated circuits, and communications. Medical terminology is also included. Students use a self-instruction text (Dennerl, 1998) and take a weekly quiz given to ensure their satisfactory progress.

The first course, BME202, starts with an overview of hospital organization and BME job descriptions that stimulates the students' interest. Students learn how to solder and desolder in the lab, and spend several hours learning electrical safety principles. In addition, the students learn to read large schematics for a single-channel ECG machine and are introduced to the twelve lead ECG configurations. Laboratory work consists of performing electrical safety tests on the classroom and an ECG machine. Next, the students perform a performance test on the ECG machine, and they learn how to find components on both the schematic and the equipment. This is followed by troubleshooting the equipment in a laboratory setting. A malfunction is placed in the machine and the entire class is taken step-by-step through the process of finding and correcting the problem. The students practice finding various problems for the remainder of their first semester's laboratory time. The remaining lectures cover subjects from transducers and electrodes, differential amplifiers, and Wilson networks to power supplies. By the end of the first semester, the student is thoroughly familiar with patient monitors and techniques for inspection and troubleshooting. Towards the end of the semester the students learn universal precautions to prepare them for their clinical internships.

BME203, given in the following semester, addresses typical biomedical equipment other than monitors, including defibrillators, electrosurgical instruments, infusion pumps, chart recorders, telemetry, central station monitors, and incubators. In the lab, each student is assigned a medical device on a round-robin basis and must test and repair it as necessary. Typical troubles are put in each device to give the student real experience. Lectures cover all the equipment used in the lab; however, the students must often work on a device before it has been discussed in a lecture. The students must then find the information they require from the available documentation and other resources, such as *Health Devices* (see www.ecri.org). The course also includes a few hours of lecture on the care and maintenance of batteries, including sealed lead acid, nickel cadmium, nickel metal hydride, and lithium ion.

Textbooks are a problem, since no single book addresses the majority of the subject matter covered in the two biomedical engineering lecture courses. Two textbooks have been tried (Aston, 1990; Carr and Brown, 1998) and each is adequate, although neither one is complete.

The clinical internship occurs during the last semester of the program. This is the capstone course and was described in detail in an article in the *Journal of Clinical Engineering* (Hines and Dyro, 1990). In this course, the students apply what they have learned during the previous three semesters in an actual clinical setting. The internship consists of one-and-a-half to two hours of lecture and eight hours of work per week. Topics covered include computerized medical equipment service and inventory systems, enteral feeding devices, infusion devices, syringe pumps, ECG monitors and machines, temperature measurement, invasive blood-pressure monitors, physiological monitoring equipment, hypo-hyperthermia devices, blood warmers, electrosurgical machines, surgical lasers, infant warmers, incubators, transport systems, pulse oximetry, oxygen monitors, and noninvasive blood-pressure monitoring. Lectures also address patient data management systems, electron microscopes, suction and vacuum devices, magnetic resonance imaging, radiology equipment, diagnostic ultrasound, hemodynamic monitoring, intra-aortic balloon pumps, defibrillators, nuclear medicine, radiation safety, pacemakers, service careers, and the moral and ethical aspects of technology in medicine.

Facilities

The program has a dedicated classroom/laboratory of approximately 1000 square feet. Equipment includes typical electronic instrumentation such as oscilloscopes, multimeters, frequency counters, function generators, and power supplies. The facility also features specialized biomedical instrumentation such as patient simulators, safety testers, defibrillator testers, electrosurgical testers, and blood pressure calibrators, as well as typical clinical instrumentation such as ECG machines, patient monitors, defibrillators, infusion pumps, recorders, and telemetry units. The total value of the equipment is approximately \$200,000, the bulk of which was purchased with three government grants. Also, the facil-

ity obtained significant donations of slightly dated equipment from local hospitals that upgraded, which is still useful for teaching.

Faculty

College faculty members teach all courses. Senior faculty members have a master's or doctoral degree and substantial teaching experience. Newer faculty members typically have doctoral degrees. Clinical engineers with at least fifteen years of industrial experience teach the biomedical engineering technology courses. One technician is assigned primarily to the biomedical engineering technology program to maintain the equipment.

Advisory Committee

Input is solicited from the advisory committee in order to ensure that the academic program produces graduates with the knowledge and skills necessary to work successfully in a clinical environment. This committee consists of representatives from hospitals, shared service companies, and medical device manufacturers. Committee members are kept abreast of any proposed changes in the curriculum, and meetings are held at least annually to discuss these changes and to obtain input on any matters that the members consider important.

Accreditation

The Technology Accreditation Commission Accreditation Board accredits the program for Engineering and Technology (TAC of ABET). This organization publishes Criteria for

Accrediting Programs in Engineering Technology annually. This publication contains general requirements for all engineering technology courses, as well as specific requirements for particular specialties. The curriculum previously described meets both the general and the specific criteria. The general criteria address such topics as adequacy of college resources and requirements for technical courses. The specific criteria cover requirements applicable only to the biomedical engineering technology curriculum. These criteria can be obtained from the ABET at the address, below:

Accreditation Board for Engineering and Technology, Inc.

ACEW Rationale and Origins

Recognition of Need

In May 1987, the 49th World Health Assembly adopted a resolution on economic support for national "health for all" strategies, in which it called upon member states to establish programs for better management and maintenance of equipment through appropriate procedures and training of personnel, and called upon WHO to provide the technical support they required to establish such programs, (WHO, 1987). This call for action reflected the growing concerns of the international community about the worldwide unsatisfactory situation regarding the management, maintenance, and use of health care equipment. Additional concerns included the deteriorating quality of health care delivery and the resulting waste of national and international resources.

The need for a workshop to train and update the leading clinical engineers from Latin America was perceived after discussions with representatives of the WHO division of strengthening of health services and the PAHO.

70

Clinical engineering education programs are underdeveloped or nonexistent in most developing countries and even in some industrialized countries. The World Health Organization (WHO), the Pan American Health Organization (PAHO), and other international bodies concerned with health care infrastructure development have collaborated with the American College of Clinical Engineering (ACCE) in the development and implementation of an Advanced Clinical Engineering Workshop (ACEW) program to address educational needs. This chapter presents a ten-year retrospective of the ACEW. Approximately 1000 participants, including faculty, represented over 50 countries in planning the program, and this chapter also includes the mechanics of the ACEW development, implementation, and review. Participants at the 18 ACEWs thus far include health care decision makers, hospital administrators, health ministry officials, nurses, allied health professionals, physicians, and clinical engineers. Results have been positive. Programs in clinical engineering education have arisen, participants have advanced in positions of leadership, governmental health technology management policies have been developed, and clinical engineers have successfully completed requirements for clinical engineering certification.

American College of Clinical Engineering

The American College of Clinical Engineering accepted the challenge of organizing the Latin American workshop and sought the help of the International Federation for Medical and Biological Engineering (IFMBE) and PAHO. Many members of ACCE travel extensively on volunteer assignments to provide clinical engineering support to developing countries. Recognizing the need to improve the level of medical device technology management and clinical engineering in the Americas and throughout industrialized and developing countries, the ACCE agreed to spearhead the development of advanced clinical engineering workshops in collaboration with other motivated organizations.

First ACEW

An organizing committee included Dr. Gloria Coe and Mr. Angel Viladegut (PAHO), Dr. Robert Nerem (IFMBE), and Mr. Frank Painter, Dr. Yadin David, and Dr. Binseng Wang (ACCE). The first ACEW was held in Washington, DC, in June 1991, at the Pan American Health Organization building (Advanced Clinical Engineering Workshop, 1991). A faculty of 19 taught 22 participants, most of whom hailed from 14 Latin American countries. Two weeks of didactic lectures were followed by two weeks of practical, hands-on technical management training in selected technologies at various institutions throughout the United States. Seven participants received funding from the PAHO Central American Project (Guatemala) while others used personal funds and institutional support. The balance of the revenue was derived from nine companies: Hewlett-Packard, SpaceLabs, General Electric, ReMedPar, Physio-Control, Ohmeda, J&J/Critikon, Siemens, and DIAL. Faculty and participants stayed at Georgetown University student dormitories.

Design, Mechanics, and Implementation

Host Needs

ACEWs are tailored to the needs of the host country or region and to the needs of the participants.

Planning

Budget

A budget is prepared that includes faculty and participant transportation, lodging, and food, as well as the cost of facilities, handout materials, translators, and advertising. Any registration fees, plus any grants and contributions from workshop sponsors, are added to the revenue column.

Agreements

Formal written agreements ensure that the workshop is financed. Advanced funding for faculty travel and *per diems* are recommended, to reduce the odds of delayed reimbursement.

Sponsors

The WHO and PAHO have provided the bulk of the financial support over the course of the ACEW program. In addition, medical device companies, publishers such as Aspen Press and the Journal of Clinical Engineering, and research organizations such as ECRI, have contributed in cash or in kind. Medical device manufacturers have underwritten the costs of lunches, dinners, and receptions and have provided staff specialists to lecture at ACEWs. Nongovernmental organizations and private foundations have given financial support to workshops.

Local Support

Local support includes translation, audio-visual, transportation, social events, photography, public relations, media relations, advertising, registration, photocopying, and meeting faculty at the airport and transporting them to workshop venues and lodging. In addition, some local organizers have arranged for a professional photographer to take pictures during the workshop that could be purchased for a nominal cost.

Design

The needs and desires of the host country or region are considered as the workshop coordinator and faculty assemble the ACEW program. The draft program is sent to the hosts, who typically will make minor adjustments.

Length of Workshop

A typical day begins at 8:30 a.m. and concludes at 5:30 p.m. It is not unusual for sessions to go beyond 6:00 p.m. and to continue into the night on topics of special interest. Certification exams occur in the evenings, which entails extra work for the faculty as they distribute, proctor, and grade the examinations. Breaks and lunch are scheduled. The time period for the didactic lecture portion of ACEWs has ranged from three days (Brazil, 2001) to two weeks (Boston, 1993). Practicum periods have ranged from one to two weeks. Faculty members report a high level of interaction and commitment to learning at all ACEWs, and that participants pay attention to and respect the faculty.

Participants

In some instances, participants are selected by a formal process, but with mixed success. Participants add much to the success of ACEWs. Although participants may be reluctant to speak up, ask questions, and interact with the faculty early in the workshop, this reticence often vanishes after the first day's welcome reception, which facilitates social interaction and intimacy. All participants enjoy a lively interaction by the end of the ACEW. This interaction creates a strong learning environment, increases the level of receptivity of the participants, and allows the faculty to learn a great deal about the problems faced by participants in their day-to-day work. Faculty members often leave these discussions enlightened by the unique and creative solutions to problems in the face of limited resources.

Faculty

Composition

Core faculty are drawn from the ranks of ACCE membership. Adjunct faculty includes selected experts on clinical engineering and medical device technology management, as well as other select fields, such as human resource development, performance improvement, motivation and morale when dealing with change, and measuring and improving client satisfaction. Faculty members from local host countries and countries in the immediate region contribute substantially to the workshop, as these individuals are usually native speakers and relate well to the participants. ACCE faculty members agree that there is much to learn from the experiences of these local faculty members. ACCE encourages all of its members to participate in the ACEW program, and it maintains a list of interested speakers. A typical composition of an ACEW faculty is three to four experienced members and one or two first-time faculty members.

Compensation and Finances

Faculty members are compensated for travel expenses, food, and lodging, but do not receive a salary, honorarium, or other compensation for their time and effort. Expenses incurred during the preparation of materials may be reimbursed, but faculty members usually rely upon the good will of their companies or businesses to defray the expense of paper, typing, reproduction, and phone and fax services. The ACCE ACEW pen is a much appreciated expense item. All workshop participants receive a pen embossed with the place and the date of the ACEW. In addition, faculty members often distribute items to the participants, including pens, small tools, books, catalogs, pocket protectors, hats, and t-shirts.

Workshop Coordinator

The ACEW coordinator maintains communication with local hosts, sponsors, and faculty. The coordinator assigns lecture responsibilities and ensures that faculty members complete their lectures and handout materials in a timely fashion. The coordinator assembles all lectures into one document, "ACEW Proceedings," for distribution to all participants. The coordinator keeps the workshop on schedule and accommodates last-minute adjustments. The coordinator gives the welcoming remarks and introduces fellow faculty members.

Faculty

Faculty members are responsible for preparing their lectures, slides, overhead projections, videos, handouts, outlines, and other workshop materials. While they are responsible for their own lectures, faculty members also draw upon material presented at previous ACEWs that is outlined in the ACEW Syllabus, described later in the chapter. Dress is business-style on the first day and casual later in the week. Jackets are quickly shed in the tropical climates, whereas ample clothing is donned in the cold, damp September in Moscow.

Venues

Hotels, hospitals, banks, universities, convention centers, retreat houses, libraries, and government buildings have all served as venues for ACEWs, as have lecture halls, classrooms, laboratories, and conference rooms.

Facilities

Workshop facilities should include the following: convenient access to lunch and break areas, adequate lighting, photocopy machines, communications (e.g., e-mail, fax, and phone), adequate seating, sound-level control, and public address system with lavalier and lectern microphones. A table should be placed in or near the classroom for last-minute handouts or papers too large to include in the ACEW Proceedings.

Presentation Format

Format of presentations varies considerably and often reflects an individual faculty member's preferred teaching style. Presentations may be individual lectures with question-and-answer periods, panel discussions, lectures with guided group discussion, lectures with exercises, break-out groups for problem solving, or role-playing, where participants play the roles of purchasing committee members, such as a hospital director, clinical engineer, nurse, physician, or finance director. Group discussions where faculty members are not present have proven to be effective for critical review of workshops. Such reviews have been a part of each ACEW and contribute substantially to quality improvement.

The lecturer may stand in front of participants at a lectern, or use a lavalier microphone and move about the room, with participants assembled about tables in a horseshoe arrangement so they can see each other's faces (Dyro, 2000).

Materials

Necessary materials for lectures might include a blackboard, whiteboard, flip chart, overhead projector, 35mm slide projector, videotape player, video projector, or laptop computer. Other helpful materials include paper and overhead transparencies, colored marking pens for overhead transparencies, a laser pointer, and a watch or timer.

Practicum

The days or weeks immediately following a one- or two-week classroom presentation are spent working and learning at a clinical engineering facility, hospital, research lab, or manufacturing site.

Site Visits

Participants and faculty visit local hospitals, manufacturing plants, and academic centers during the course of a one- or two-week ACEW. Such visits are preferably arranged and scheduled before the ACEW, but they can be arranged during the ACEW as need and interest dictate.

Evaluation

Evaluation forms are completed on the last day of the ACEW, and open discussion elicits comments and criticisms from the participants.

Archiving

ACEW activities are routinely documented through published reports. Handouts and lecture materials are kept by faculty members for use in future ACEWs. Materials are often in the form of technical and scientific article reprints, photographs, CDs, slides, tapes, and overhead projections, but PowerPoint® presentations have gained favor with faculty, and they are encouraged to use the program, since electronic storage of lecture presentations facilitates dissemination of ACEW content.

Typical ACEW

Planning Sessions

Either the WHO or the PAHO identifies the need for an ACEW. Individual countries often request ACEWs when they recognize the impact they have on the health care systems of neighboring countries. Once budgetary constraints are analyzed and feasibility is determined, WHO or PAHO contacts the ACEW workshop coordinator for scheduling. The coordinator, host country, and sponsoring agency determine a date, and planning begins. The coordinator identifies the faculty and begins to plan the ACEW.

Lecture Preparations

Faculty members complete their lectures and handout materials before the ACEW, and they are encouraged to present them using PowerPoint®.

Arrival and Organizational Meeting

Upon arrival at the ACEW site, the faculty members assemble to discuss the upcoming workshop. Particular concerns include last-minute changes in the program; requests for additional modules; requests for local participation; site visits; and schedules of dignitaries, health officials, and the press. At this time, last-minute adjustments are made to the orientation and emphasis of the lectures. Special requests are considered and incorporated if possible. No ACEW schedule has been followed to the letter, because changes always arise and demand flexibility on the part of the faculty.

First-Day Ceremonies

A typical first day consists of the following: The workshop coordinator, representatives of host organizations, local sponsors, dignitaries, politicians, and health officials give introductions. Faculty introduce themselves with a brief biographical sketch and a description of the subjects to be covered. The coordinator gives a presentation of the workshop objectives and describes the succeeding days' schedules in detail. The schedule for the week is distributed, along with the compendium of lectures and their supporting documentation. Other handouts are also distributed at this time. After the end of formal lectures on the first day, faculty and participants enjoy a welcoming reception. Establishing rapport with the participants at the reception promotes increased information exchange throughout the remainder of the workshop. Such social functions result in long-term associations, to the benefit of faculty and participants.

Typical Workshop Day

Workshops begin approximately at 8:00 a.m. and end at 5:00 p.m., with morning and afternoon breaks and lunch breaks taken during the day. Lectures should not last beyond 1½ hours without giving participants an opportunity to stretch. Lectures can include any of a number of topics contained in the ACEW Syllabus (Dyro and Wear, 2001), and detailed descriptions of the contents of past ACEWs have been published (Advanced Clinical

Engineering Workshop, 1991; Wear, 1995; Dyro, 1996; Dyro, 1999a; Dyro, 1999b; Judd and Dyro, 1999; Dyro, 2000c; Dyro, 2000a; Dyro, 2001; Clark, 2002).

Social Programs

Social programs form an integral part of most ACEWs. These might include a simple reception with coffee, tea, and snacks, or a formal banquet. Local hosts often arrange tours to scientific, medical, historic, cultural, architectural, and environmental sites. While most faculty members are present during each other's presentations, arrangements can be made for an individual faculty member to spend some free time visiting the local attractions (see Figure 70-1).

Closing Ceremonies and Evaluation

Certificates of participation are awarded to participants, and faculty may also receive them. It is not atypical for participants to recognize the contributions of the faculty with presentations of small gifts such as handcraft items or books describing the city or country. Closing ceremonies also include group photographs.

Misadventures

Visas

Moscow's Sheremetyevo Airport has two terminals: Terminal One and Terminal Two. A faculty member, Bob Morris, flew from China to Moscow, where he was to meet fellow faculty member Al Jakniunas, who had Bob's visa. Al waited at Terminal 2 and Bob arrived at Terminal 1. With no visa, Bob went directly to a detention cell and was booked on the next flight back to China (Figure 70-2). Hours later, after scouring the airport, the ACEW search party spotted Bob peeping through the window of his cell. Visa in hand, the workshop went on.

Medical Emergencies

Faculty member Al Jakniunas became sick with an intestinal problem en route to Moscow (Figure 70-3). The chief surgeon at the top military hospital in Moscow, who was a workshop participant, ordered him to the hospital for emergency surgery. After four hours under the knife, Al's intestines were repaired, and he recovered completely during his two-week recuperation in the VIP suite (Dyro, 1999b).

Gastrointestinal afflictions from inadequately cleaned food (e.g., oranges washed in the fetid tributaries of the Nile) are not uncommon during travels to foreign lands.

A pre-occurring emergency, such as when illness struck one faculty member days before the Mexico ACEW, or during an ACEW, means that healthy faculty pick up the slack and make the presentations in place of the afflicted. The author had a close call, but, fortunately, the local host facilitated the services of a skilled endodontist to treat an abscessed tooth.

Participants are not immune to emergencies—an asthma attack found a Panama ACEW participant in the hospital.

Health insurance is highly recommended. In fact, WHO contracts include insurance coverage for all faculty.

Air and Ground Travel

During the practicum phase of the first ACEW, 12 participants packed into Frank Painter's station wagon for a site visit to New York City. On the way from Trumbull, CT to their destination, the overloaded station wagon's suspension system collapsed.

Tom Bauld relates his account as a first-time faculty member at the Panama ACEW (Bauld, 2001). Airplane maintenance delays meant a missed flight and an overnight at the airport hotel. A gang that was headquartered in a hotel not far from the ACEW venue, was arrested and charged with plotting to assassinate Fidel Castro, who was attending a Latin American summit. While walking through the national park under a giant palm, a branch fell, narrowly missing us.

Lost or delayed suitcases are not uncommon. Bob Morris was clothed entirely in apparel borrowed from four others on his team.

Watch those potholes and burros and racecar drivers! Local roads, traffic conditions, and drivers may differ in quality from those to which faculty are accustomed.

Unexpected and Memorable Events

Terrorists bombed apartment complexes in Moscow during the week of the ACEW. The bombing near the American Embassy in Lima kept the faculty in its hotel, thus severely curtailing sight-seeing (Painter, 2002).

A flash fire during the ACEW in Quayaquil, Ecuador tested the participants' accident/incident investigation and root cause analysis skills (Dyro, 2001). During a presentation on the systems approach to accident/incident investigation, a fire broke out in a food pantry immediately outside the classroom. Acrid black smoke filled the area, sending gasping faculty and participants in search of fresh air. After the fire was extinguished and the smoke cleared, the presenter assigned teams of participants to put into practice what they had just learned. The ensuing investigations yielded results that were then presented to the workshop class. Faculty served to critique the presentations and to guide the class in contributing their insights into the analysis.

The Beijing ACEW faculty nearly disappeared on the Great Wall of China. Fortunately, one member of the faculty, Dr. Binseng Wang, was somewhat familiar with the native language and obtained the necessary directions back to the workshop.

The timing of breaks during the Nepal ACEW was often determined by power outages, which prevented projection equipment from working (Wear, 2001).

Everyone would do well to use the philosophy practiced by veteran world traveler and educator Bob Morris. During his illustrious career, he often found himself in difficult situations about which he could do nothing. He maintained serenity and tranquility, for to do otherwise (e.g., to become angry or depressed) would not change the situation.

ACEW Retrospective

A total of 19 ACEWs have been presented since the first ACEW in Washington, DC in 1991. Following is a list of those ACEWs.

List of ACEWs and Published Workshop Reports

1. Washington, DC—June 1991 (Advanced Clinical Engineering Workshop, 1991)
2. Boston—May–June 1993 (Second International Advanced Clinical Engineering Workshop Executive Summary, 1993; Wear, 1995)
3. Beijing—November 1995 (Dyro, 1996)
4. Washington, DC—June 1997 (Advanced Workshop, 1997)
5. Mexico City—November 1998 (Dyro, 1999c)
6. Hartford, Connecticut—June 1999 (Dyro, 1999a)
7. Moscow—September 1999 (Dyro, 1999b)
8. Cape Town, South Africa—November 1999 (Judd and Dyro, 1999)
9. Santo Domingo, Dominican Republic—March 2000 (Dyro, 2000c)
10. Chicago, July 22–23, 2000 (Dyro, 2000b)
11. Vilnius, Lithuania—September 18–22, 2000 (Dyro, 2000a)
12. Panama City, Panama—November 13–17, 2000 (Hernández, 2001; Bauld, 2001)
13. Guayaquil, Ecuador—March 26–30, 2001 (Dyro, 2001)
14. Nepal—April 9–13, 2001 (Wear, 2001)
15. Havana, Cuba—May 2001 (David, 2002)
16. Brazil—June 4–6, 2001 (Wear, 2001)
17. Costa Rica—February 25–March 1, 2002 (Clark, 2002)
18. Lima, Peru—March 18–22, 2002 (Painter, 2002)
19. Guayaquil, Ecuador—September 9–13, 2002 (Gentles, 2002)

ACEW Syllabus

Having realized the value of ACEWs, WHO supported the development of the ACEW Syllabus (Dyro et al, 2003). No two ACEWs are exactly alike, because educational needs and health care development efforts vary from one country to the next. Advances in technology and practices continue to change with time. The Syllabus includes a detailed description of the many models that constitute an ACEW.

WHO Specifications

In order to best match the needs of the host country or region to the educational content of the ACEW, WHO determined that the Syllabus should contain a shopping list of various topics that address all aspects of clinical engineering and health care technology management. Topics include those suitable for the educational needs of all levels of participants in the health care infrastructure; i.e., health ministry officials, hospital administrators, directors of clinical engineering, clinical engineers, educators, and allied health professionals. The Syllabus then can be referenced during the course of ACEW planning between host region or country and ACEW faculty.

Contributors

Under WHO direction and specification, the Syllabus contains a representative outline of a two-week ACEW. The following faculty members have served on ACEWs and have provided the bulk of the material for the Syllabus: Tobey Clark, Yadin David, Joseph Dyro, Jonathan Gaev, David Harrington, Alfred Jakniunas, George Johnston, Thomas Judd, Robert Morris, Frank Painter, Mladen Poluta, Henry Stankiewicz, Binseng Wang, and James Wear.

Contents

The 232-page Syllabus comprises some 65 modules, all of which have been presented at least once at one of the 19 ACEWs presented to date. Each individual module comprises the following: learning objectives, summary of the lecture, lecture outline, and references. The modules are grouped under the following areas: introduction, maintenance and service management, national health care equipment management policy, health facility needs assessment and planning, impact analysis, selection and procurement strategies, information systems, technology assessment, resource allocation, human resources development, safety, risk management and quality improvement, utility systems, troubleshooting, technical lectures on medical devices, and summary of workshop goals and objectives. The Syllabus addresses virtually all aspects of clinical engineering and health care technology management, and therefore represents a valuable guide for any educational program in these fields.

Value Analysis

As a direct result of the ACEWs presented to date, programs in clinical engineering education have arisen; participants have advanced in positions of leadership; governmental health technology management policies have been developed; and clinical engineers have successfully completed requirements for clinical engineering certification.

Indicators

Number of ACEWs 19

Number of Participants: Over 1000

CCE Exams: Over 20

Career-Ladder Ascent

Several participants have risen in their institutions' hierarchies or have forged initiative in the health care infrastructure, such as new medical device management companies. One participant is now special advisor to the president of Mexico; another has founded a successful shared services program in Brazil.

Academic Programs

Intent to establish academic programs in clinical engineering has intensified, and discussions between ACEW faculty and academic institutions in host countries for program development are underway.

Evaluations

Participant evaluations of the ACEW have been consistently excellent.

Clinical Engineering Advocacy

While difficult to measure, promotion of the profession of clinical engineering occurs. Name recognition is increasing. Governmental bodies are incorporating recommendations made during the course of ACEWs into laws and regulations.

Advantages and Disadvantages

Faculty

While traveling, the faculty can visit with relatives in foreign lands, gain appreciation for local customs, cuisine, and culture, improve dancing and language skills, foster cordial relations with professionals around the globe, and learn from participants and faculty from host and other countries. Although the work is hard, and the travel long, and although time is lost when one is away from busy projects at home, the overall consensus of the faculty is that participation in ACEWs is a broadening experience, a wonderful change of pace, and an opportunity to visit other parts of the world. The visits are distinctly different in that the hosts provide personal insight rarely obtained when one travels as a mere tourist.

Participants receive world-class clinical engineering education in their own countries. This minimizes their expenses. Often, the costs of air travel, accommodations, and living outside of their countries are prohibitive. Education now becomes affordable.

Infrastructure in Developing Countries

Most developing countries have rudimentary, at best, or nonexistent, at worst, health care technology management policies.

Networking

Participants are encouraged to maintain contact with faculty. Internet access enhances networking. Faculty have hosted participants who visit the United States subsequent to ACEW attendance.

Resource Expenditure

ACEWs are a cost-effective way of providing world-class education to those who are most likely to benefit from it.

Conclusion

ACEWs have demonstrated a positive influence on the development of clinical engineering education and practice around the globe. ACEWs have heightened the awareness that health care technology management is a fundamental building block in a nation's health care system. The ACEW has shown itself to be an effective means to transfer information in a relatively short period of time at a modest expenditure of financial resources. The ACEW will continue to be utilized well into the future. Among those countries in which the need and desire for ACEW workshops has been identified are the following: Jamaica, Mexico, Venezuela, Kazakhstan, Kyrgyzstan, Mongolia, Tajikistan, Turkmenistan, Uzbekistan, Moldova, India, Ukraine, and Armenia.

Advanced Health Technology Management Workshop

Thomas M. Judd

Director, Quality Assessment, Improvement and Reporting, Kaiser Permanente Georgia Region, Atlanta, GA

Joseph F. Dyro

President, Biomedical Resource Group Setauket, NY

James O. Wear

Veterans Administration North Little Rock, AR

Health technology management leaders from twenty sub-Saharan African countries participated in an advanced health technology management workshop in Cape Town, South Africa, from November 8–12, 1999 (Judd and Dyro, 1999). Eight American College of Clinical Engineering (ACCE) members were among the faculty presenting to approximately 65 attendees. This workshop was one in a series of Advanced Clinical Engineering Workshops (ACEWs) organized by the American College of Clinical Engineering. Thomas Judd (ACEW coordinator), James Wear, Frank Painter, Bob Morris, Binseng Wang, and Joseph Dyro (United States) were joined by fellow ACCE members Andrei Issakov (Geneva, Switzerland) and Enrico Nunziata (Mozambique).

On the last day of the workshop, faculty, participants, and sponsors critically reviewed the five-day event. The workshop focused on advanced health care technology management: planning, funding and management of health care technology and the required infrastructure to achieve optimal outcomes. The evaluation reviewed workshop goals and objectives, collected an accurate list of participants and faculty with their contact information, and summarized key messages from each workshop presentation. The evaluation meeting also solicited recommendations from participants for improving future workshops as well as recommended next steps for follow-up by the participants, their home countries, and the World Health Organization (WHO), and gave participants an opportunity to offer feedback on workshop messages and logistics. This chapter presents both a detailed description of the Cape Town workshop itself and the methodology for the critical review of all ACEWs and similar workshops.

Organization and Participants

The workshop was organized by the American College of Clinical Engineering (ACCE), World Health Organization (WHO), African Federation for Technology in Health care (AFTH), Department of Health of South Africa, and South African Medical Research

Council (SAMRC) in association with the International Federation for Medical and Biological Engineering (IFMBE) and the International Federation of Hospital Engineering (IFHE). The event was cosponsored by the Association for Appropriate Technologies (FAKT), European Union (EU), Finnish International Development Agency (FINNIDA), German Technical Cooperation Agency (GTZ), and Oregon Health Sciences University (OHSU).

Welcoming and opening remarks were made by the following dignitaries: Peter Heimann (SAMRC), director of the WHO Collaborating Centre for Essential Technologies in Health and secretary-general of AFTH, as well as Andrei Issakov (WHO), Robert Morris, past president, ACCE, Mladen Poluta, director of the health care technology management program at the University of Cape Town and chairman, IFMBE working group on developing countries, Nonkonzo Molai, director of health technology policy, on behalf of A. Ntsaluba, director-general of the department of health of the Republic of South Africa; Nico Walters (MRC) on behalf of M.W. Makgoba, MRC president, and Bernard Shapiro, IFHE secretary-general.

Participants included 12 instructors, eight of whom were ACCE members, and 65 attendees who were health technology management leaders from 20 sub-Saharan African countries.

Goals and Objectives

The purpose of the critical review is to enable the participants to understand clearly workshop goals, objectives, and key messages. In this case, the workshop goal was to understand how to partner with other participants in the sub-Saharan Africa region and other supporting organizations to implement the key health care technology management (HTM) principles, practices, and messages learned during the workshop.

The regional WHO director determined that health technology policy in Africa should address technology management, human resources development, research and communi-

ation, and access to information. The overall goal of the workshop was to build strength and capacity for health technology management (HTM) in Africa. The prime objectives were to raise awareness of HTM for health decision makers at policy level in the region, to provide the latest information and to expand awareness of fundamental and advanced concepts and methods of HTM, and to share positive HTM experiences with decision-makers from other countries in the region. The workshop addressed planning, funding, and management of health care technology and the infrastructure required to achieve optimal outcomes.

In February 1999, the WHO regional director stated that priority interventions for developing health technology in Africa should address the following issues:

1. Technology management
2. Human resources development
3. Research and communication
4. Access to information

The opening address by the department of health at the Cape Town ACEW in South Africa on November 8, 1999 highlighted the following:

The level of health service delivery has not notably improved in spite of considerable investment in importing new technologies and the operational expense of supporting these technologies. For example, the lack of equipment maintenance and repair is a major barrier to providing effective care, and stems from poor planning and acquisition and procurement. The most important intervention is ensuring a stable supply of competent technology managers. It is the desire of the department of health that the workshop teach decision makers and planners to deal with complex issues of planning, life cycle, transfer, management, and utilization of health technology, so that organized plans for education, training, and placement of HTM professionals can be developed. This workshop is intended to impart skills to the HTM community to ensure and enhance the safety of health technologies and facilities. HTM is one of the major expenses in our health care system within the area of resource mobilization. The broad framework for comprehensive health care technology (HT) policies has been created. An HT system composed of acquisition, management, planning, and assessment as subsystems is top priority. The major short-term strategic action is a comprehensive national HT audit. Another action is field testing of the Essential Health Technology Package (EHTP) software. The results of these two actions will determine the level of government intervention required.

Major Topics Presented

Technology Trends and Impacts

The link between health outcomes (life expectancy) and a country's economic system is clear. To understand and improve health system performance, health data are needed for analysis. Disability adjusted life years (DALYs) are an effective measure of disease burden (Murray and Lopez, 1996). There is quantitative evidence of the positive impact of HTM on health system performance. Various technology trends can impact future delivery systems for devices and supplies, logistics, medical procedures and techniques, and sites of appropriate care.

National Health Technology Management Policy and Communication Plan

Major changes in the sophistication and complexity of medical technology are expected in the next decade. Management capacity will determine a country's ability to absorb technology. Health care technology (HT) policy is indispensable and will provide the framework for health technology management (HTM); it drives the entire system and its ongoing improvement.

WHO Guidelines for Formulation of National Health Care Equipment Policy

Generic guidelines and implementation documents covering both process and content have been drafted to assist countries in developing and monitoring national HT policies (WHO, 1999). The HTM process is complex; its policy must address all issues of the HT life cycle.

Managerial Competency Requirements

The workshop participants discussed managerial competency required for the effective use of technology and health care planning for district health management in Africa. Active learning is the best method for training technology managers, with incremental changes expected over time. Leadership needs an effective district-level information system to manage by fact. The book entitled *Yenza* (Human, 1998) served as a blueprint for management transformation.

Macro Technology Assessment and Strategic Planning

Macro technology assessment includes evaluation of safety, efficacy, and cost-effectiveness of new procedures and equipment. It is appropriate in developing countries, and needs to be done to ensure "evidence-based" decision making. It creates a bridge between science and decision making and is the only real contribution towards sustainability. Questions to consider are when new technologies should be adopted and older ones replaced, which clinical services should be offered to address the needs of the patient population, and what changes should be introduced to the existing clinical services. Good

sources of information on technology assessment include ECRI (www.ecri.org) and the International Society of Technology Assessment in Health Care (ISTAHC).

Micro Technology Assessment

Micro technology assessment includes the evaluation of equipment to be purchased for a single hospital. For example, one hospital developed a multidisciplinary committee for capital equipment assessment, including the evaluation of information available from clinical engineers. The content of technology audits was described in *Medical Technology Management* (David and Judd, 1993). Examples of techniques for conducting the audits came from Senegal, South Africa, and Namibia.

Planning, Selection, and Procurement Strategies

Other key issues discussed at the workshop included the importance of planning, life cycle cost or cost of ownership, pros and cons of the purchase process, evaluation of the need, impact, costs, and benefits of new technology, evaluation of available products on the market, and acquisition of the best product to meet the facility's needs. Alternatives such as lease, rental, and donation were also discussed.

WHO Essential Health Care Technology Package (EHTP)

The EHTP represents a new and unique decision making tool for effective HTM. The EHTP links human resources, medications, equipment, and facilities for diagnostic and therapeutic procedures. It is adaptable and appropriate for developing countries and is available to them at no cost from WHO. The package focuses on interventions and addresses all the necessary requirements; it allows for various scenarios and can be used to determine the criticality of equipment in the provision of care (see Chapter 45).

Health Care Equipment Donations

Donation guidelines proposed by FAKT (1994), ACCE (1995), and others have been combined into draft WHO guidelines (1997), which can be adapted to each country's (or organization's) circumstances. The WHO guidelines formalized the communication link between donors and recipients. Forms requiring essential information are provided. Donations play an important part in providing needed services; up to 80% of the equipment in some countries arrives through donations. Donations must be managed for appropriateness and effectiveness.

Provider-Vendor Relationships

Health care organizations should seek out manufacturers and vendors who have their interests in mind. Everything is negotiable; a good relationship benefits both parties. Health care organizations can improve the quality of the service received from the suppliers by communicating clearly, documenting expectations, and supporting good vendors.

Maintenance and Service Management

A comprehensive inventory is the foundation of a good management program. Gathering financial data along with service activity helps hospitals evaluate actual service costs. Data and the ability to act in response to data are needed for effective service management. Departments that demonstrate cost savings can create resources in an environment of fixed resources. Examples of resource creation and service management were provided through two case studies. Technology management is a developing process; one can start small and then grow.

Budgeting and Financial Reporting

Key issues presented were budgeting for an in-house clinical engineering department, cost recover methods, and financial planning for a for-profit service company (see Chapter 48).

Human Resources Development

Planning and Management

Key issues discussed included the roles and responsibilities of biomedical equipment technicians and clinical engineers, ways managers can improve the clinical engineering program, ways to improve the productivity of maintenance personnel, and ways to determine the personnel requirements of a health care technical service (HCTS).

Training, Continued Education, and Use Training

Professional development of clinical engineering personnel through education and professional organizations was discussed. Appropriate user training can enhance health outcomes.

Health Care Technical Services (HCTS)

HCTS provide a structure for a decentralized, countrywide provision of HTM services. Representatives from Kenya, Malawi, Cameroon, Senegal, Nepal, Mozambique, and Tanzania presented case studies of various models. Key contributors to development of these models in the region include German Technical Cooperation (Deutsche Gesellschaft für Technische Zusammenarbeit (GTZ)), FAKT GmbH, European Union (EU), and FINNADA. Decentralization has necessitated a rethinking of older models and has allowed greater opportunities for public and private mix of ways to provide services.

Safety, Risk Management, and Infection Control

Additional issues presented included infection control, along with maintenance of medical equipment, protection of the staff, the identification of risks and hazards by incident review, risk reduction, and sharing. The use of a systems approach and personal vigilance for device problems, frequent assignment of technology managers as radiation safety officers, an increase in training related to user errors, a review of international and US safety standards and regulations, and a discussion of liability insurance were included.

Quality Assurance and Improvement

Issues of medical equipment quality assurance and improvement concepts were presented, including user and service training and updating and regulatory compliance (e.g., recalls, tracking, reporting, and patient incident investigations). Quality of care improves through development of appropriate infrastructure, use of evidence-based medicine to drive care, provision of data feedback to practitioners on the effectiveness of their care, and creative use of the EHTP.

Computerized Management Systems

A computerized equipment management system is essential to handle a large inventory. The workshop speakers described the design principles and philosophy and the basic elements of a countrywide system for developing countries. Service costs, productivity, and quality-improvement initiatives require a computerized data-analysis system, and the purchase price of hardware and software is only part of the commitment for use of this system.

Utility Systems

HTM procedures should include utility systems requirements. Clinical engineering should be involved in the design of both facilities themselves and their utility systems to increase awareness of utility challenges and possible solutions. Infection control is important with regard to all utilities, particularly HVAC and water.

- Electrical distribution
- Heating, ventilation, and air conditioning systems
- Medical gas and vacuum systems
- Water systems
- Sterilization
- Maintenance procedures

Professional Registration and Certification

Certification is the only professional standard available to evaluate practicing clinical engineers and biomedical equipment technicians. Certification is a voluntary, peer-reviewed process, not a mandatory countrywide registration. Developing countries have used certification to increase recognition of clinical engineers and to measurably raise the level of health care provided.

Outsourcing of Service Management

The workshop speakers also discussed the extent of outsourcing, including full, partial, and management services only. Elements of successful outsourcing include thorough knowledge and information, good initial data, and continuous monitoring of the relationship.

Medical Equipment Troubleshooting

A centralized approach with readily understood, practical techniques was presented, and participants received a guide to troubleshooting medical equipment.

Recommendations

Points Workshop Organizers Should Consider

- Participants' stated workshop objectives:
 1. Training in the basic principles of health technology management used in the United States
 2. Exchanging information and experiences with colleagues from other countries
 3. Promoting the growth of the profession
- Content issue: Provide an introduction on preparing action plans (2- to -3year short-range plans), operating plans (6 months to 1 year), detailed activity plans to monitor work, and reference terms for studying the sector.
- Faculty meetings: Conduct these during the workshop to ensure that presentations are on track.
- Notebooks: Use tabs so that presentation materials are clear.
- Notebooks: Ensure that presentation materials are spell-checked.
- Notebooks: Whenever possible, provide presentation materials prior to the presentation.
- Faculty preparation: Recognize where different presentations will cover the same materials to discern the advantages and disadvantages of overlap.
- Faculty preparation: Consider ways to have faculty better prepared to understand the regional situation prior to the workshop.
- Presentation style: Consider using case studies and group exercises to reinforce the presentation materials.

- Presentation style: Demonstrations are extremely helpful.
- Participant assessment: Set aside specific times for participant feedback to assess how well participants are learning and how to improve; conduct evaluation at the conclusion of the workshop.
- Participant follow-up: Ensure that contact information is provided for all participants.
- Participant follow-up: Ensure that photographs taken at the workshop are provided for all participants.
- Faculty follow-up: Prepare a handbook of standard workshop presentation materials for participants and others to use.
- Clarify order of presentation of the workshop earlier for faculty convenience.
- Recognize how learning can diminish with long workshop days.
- Ensure that participants have time to network with the speakers and each other.
- Ensure that presentation scheduling leaves time for participants to ask questions and share their experiences.
- ACCE and WHO should consider development of a communications/publications/document retrieval service for African health technology managers of clinical engineering with information from 1980 to the present.
- Recognize that participants appreciated and benefited from the presentations, and from the wealth of experience of the faculty. "We have been given a vision of how we can find a way to our solutions," one participant said.
- Include more discussions of participants' experiences, not only faculty experiences, to add balance.
- Participating countries' Ministries of Health (MOH) should receive objectives prior to the workshop to aid in the selection of the most appropriate participants.
- The WHO Essential Health Technology Package (EHTP) review should be expanded.
- Consider using a professional facilitator in workshop to widen participant discussion; continue to bring in an outside management expert/faculty member.
- Provide a participant list with key job responsibilities and local objectives related to the workshop.

Participants and Countries in Africa

Participants in African workshops should consider the following:

- Join the African Federation for Technology in Health care (AFTH)
- Short-term goals:
 - Formulation of a national policy through a task force
 - Evaluation of the WHO EHTP
 - Organization of local workshops (AFTH/MRC/UCT)
- Development of a plan for collaboration with the WHO through the AFTH.
- Sign up for INFRATECH@LISTSERV.PAHO.ORG, worldwide e-mail distribution.
- Distribution of the ACCE News, the newsletter of the ACCE, by e-mail and otherwise.
- Distribute comments, feedback, and follow-up to participants, via Infratech e-mail, regular mail, and AFTH website.
- Share workshop information within participating countries and with those who were unable to attend.
- Note that participants in the African workshop expressed concerns including: "Will countries take action on what we learned and recommendations at this workshop?" "What outside pressures will there be on monitoring and enforcement from the WHO or from Africa?"
- Develop strategies for the training of health technology managers at the "grass roots" level; build upon concepts discussed in *Yenza* (Human, 1998).
 - Actual requirements
 - How to form partnerships, as the Pretoria, South Africa, Technicon program has done
- Establish Senegal regional training sites and a web site, as well as a center to collaborate with the WHO.

World Health Organization (WHO)

After the Africa workshop, the WHO considered the following:

- EHTP: Encourage audits and integrate audit technology
- Consider strategies for how countries are monitored against resolutions:
 - By individuals
 - By WHO representatives at the WHO regional planning meetings
- Facilitate distribution of workshop participant feedback and country situation analysis 6 to 9 months after the workshop

Evaluation

Survey Questions

A survey was distributed at the end of the fourth day of the Africa workshop and collected at the end of the workshop the next day, with the assumption that all participants knew enough English to understand and respond to the questions.

The following eleven questions were asked:

1. What were the best three parts of the workshop program?
2. What three parts of the workshop program were the least useful to you?
3. Rate the presentations in general by checking one of the following: 1 = poor to 5 = excellent
4. Check how useful the workshop presentations will be to your job: not useful/useful/very useful
5. How will you use this information when you return to your job?
6. Rate the usefulness of the handout materials: poor/fair/good/very good/excellent

7. How would you improve the handouts?
8. List some topics that you would have liked to discuss in the workshop.
9. Check the categories of people that you would recommend to attend this workshop.
10. Would you recommend this workshop to others?
11. What is your role in the health care delivery system in your country?

Survey Results

The overall results of the evaluation are very good. There is no doubt that the participants enjoyed the workshop, which is the criterion for a level-one evaluation. The participants were not evaluated on knowledge gained, but the survey suggests that they gained useful information. Thirty-one of the participants returned the surveys, and the following summary includes percentage responses where possible.

1. What were the three best parts of the workshop program?

The following is a summary of the topics in the order presented. Any topics not listed did not receive any rating. If a topic is not rated, it does not mean that it was not good, but only that no one rated it as the best.

- 10% Technology Trends and Impacts
- 23% National Health Technology Management Policy and Communication Plan
- 6% WHO Guidelines for Formulation of National Health Care Equipment Policy
- 23% Managerial Competencies Required for the Effective Use of Technology
- 6% Y2K Issues Panel
- 29% Macro Technology Assessment and Strategic Planning
- 3% Micro Technology Assessment
- 23% Planning, Selection, and Procurement Strategies
- 13% WHO Essential Health Care Technology Package
- 16% Health care Equipment Donations
- 10% Manufacturer–Vendor Relationships
- 35% Maintenance and Service Management
- 13% Budgeting and Financial Reporting
- 16% Human Resources Development (Planning and Management)
- 6% Safety, Risk Management, and Infection Control
- 6% Quality Assurance and Improvement
- 3% Utility Systems Panel

The topic of greatest interest was the maintenance and service management. Bob Morris was the only faculty member mentioned for his presentation, which related to this topic. The policy and planning topics were rated the next most important to the participants.

2. What three parts of the workshop program will be the least useful to you?

The following is a summary of the least useful topics in the order presented. Any topics not listed did not receive any comments. The fact that a topic is listed does not mean that it was a bad topic or poorly presented, but that it was the least useful to one or more of the participants. In some cases, the same topics appear here that were listed above as best parts of the workshop.

- 3% National Health Technology Management Policy and Communication
- 6% Managerial Competencies Required for the Effective Use of Technology
- 6% Health Care Planning for District Health Management in Africa
- 10% Y2K Issues Panel
- 3% WHO Essential Health Care Technology Package
- 6% Manufacturer–Vendor Relationships
- 26% Budgeting and Finance Reporting
- 3% Human Resources Development (Planning and Management)
- 6% Safety, Risk Management, and Infection Control
- 6% Quality Assurance and Improvement
- 10% Computerized Management Systems
- 32% Utility Systems Panel
- 13% Professional Registration and Certification

The utility systems panel was, by far, the least useful, and it probably was the weakest topic in the program. Budgeting and financing was the next least useful topic mentioned. Because most of the participants were government representatives, they had difficulty relating to some of the concepts.

3. Rate the presentations in general by checking one of the following:

Poor 0% Fair 0% Good 42% Very Good 48% Excellent 10%

All participants thought that the presentations were good to excellent, with 58% rating the presentations either very good or excellent. While the survey did not distinguish among the presenters, no presentation received a rating of “not good.”

4. Check how useful the workshop presentations will be to your job.

Not Useful 3% Useful 55% Very Useful 42%

The overwhelming majority of the participants (97%) felt that the workshop presentations would be useful in their jobs.

5. How will you use this information when you return to your job?

- 35% Increase decision makers’ awareness of the importance of HCTS.
- 19% Formulate and implement an HCTS program policy.
- 16% Share the information with counterparts to see whether it applies in my country.

- 10% Lecture students and conduct my own workshop.
- 6% Apply the guidelines in planning, procurement, outsourcing, and equipment policy.
- 6% Share information with medical equipment and health care technologists.
- 6% Improve my weak areas in the field.
- 3% Integrate all the district maintenance units in a coherent system.
- 3% Set up a central unit for procurement strategies.
- 3% Link up with the Health Infrastructure Division on ways in which it fits into the National Health Policy and Plan under SWAP.
- 3% Develop a workshop of training and equipment activities.
- 3% Advocate for training and continued education in HCT.
- 3% Encourage purchase of better equipment management in my area.
- 3% Change some work procedures to improve work safety.

The percentages add up to more than 100% because some participants indicated more than one planned use of the workshop information on returning to their jobs. Similar responses were combined to assess the overall impact of the workshop. More than one-third of the participants planned to use the information to encourage decision makers to implement a Health Care Technology Policy.

6. Rate the usefulness of the handout materials.

Poor 0% Fair 13% Good 45% Very Good 42% Excellent 0%

None of the participants rated the usefulness of the handout materials as poor or excellent, and only 13% rated them as fair. Most of the fair ratings also commented on the need for better organization and more timely availability. Since 87% rated the handout materials as good or very good, the participants should have been able to use these materials to accomplish the items they listed in question 5 when they returned to their jobs.

7. How would you improve the handouts?

- 35% Make handouts available at beginning of workshop
- 19% Organize handouts with dividers
- 19% Make handouts more condensed, and include references
- 3% Edit the overheads into pictures and captions
- 3% Make handouts available electronically
- 3% Add more detailed material
- 3% Provide more tools
- 3% Provide a list of information services and web sites
- 3% Print double-sided to reduce volume of paper

The participants obviously wanted the handout materials at the beginning of the workshop, and organized so they could follow with the lectures. Nineteen percent wanted fewer materials, but more references so they could research additional information on their own. Some participants noted specifically that material that was not covered in the lectures should not be in the handouts. These percentages do not add up to 100% since some participants made more than one comment and some made no comments.

8. List some topics that you would have liked to discuss in the workshop.

- 19% Situation analysis of the health technology management in each country
- 6% Action plans and workshop resolutions
- 6% Strategies to convince the government that we are a big part of health care in South Africa
- 3% WHO’s health technology policy in the African region
- 3% Human resources development for specific countries
- 3% More practical issues on topics like quality assurance or risk management
- 3% More of the policy and planning role, less on managing and implementing
- 3% Generic specifications to assist in the procurement of medical equipment
- 3% Practical setting-up of maintenance/engineering workshops
- 3% In-house maintenance vs. outsourcing
- 3% Case studies on productivity and effectiveness of health care provinces
- 3% Southern Africa Development Community training using pooled resources
- 3% Training of technicians and users
- 3% How to interface with decentralized and privatized health facilities
- 3% Medical technology management as part of the whole health-district system
- 3% Presentations by health equipment manufacturers
- 3% Information on certification of clinical engineers and BMETs in the United States
- 3% WHO’s Essential Health Care Package

Most of the additional topics that participants wanted focused on individual countries’ experiences. This would have allowed for more sharing and might have given them better ideas for specific solutions to their local problems. The percentages do not add up to 100% since some did not list any topics and some listed more than one.

9. Check the types of individuals to whom you would recommend this workshop.

Manager 71% Engineer 77% Planner 58% Health care Administrator 58%
Technician 35%
Others—Politician, Advisor, Nurse, Decision Maker, Policymaker, Manufacturer

These recommendations probably reflect the jobs of the participants. Some thought that the attendees should be in pairs of a technical person and an administrative person. Others said that they would have liked to have the workshop agenda beforehand, to help in the selection of the attendees.

10. Would you recommend this workshop to other people?

Yes 97% No 0% Maybe 3%

This is probably the most significant result of the evaluation. If 97% of the participants would recommend the workshop to others, they must have found the information useful.

11. What is your role in the health care delivery in your country?

The jobs of the participants were grouped below into "technical or engineering" and "administrative or planning" roles. However, this grouping may not be accurate, since engineers may function in both administrative and planning positions. Conversely, participants who are not engineers might also have HTM roles.

Technical or Engineering

- Clinical engineering coordinator (private hospital)
- Electronic engineer in medical equipment maintenance
- Engineer, provincial maintenance section
- Head of biomedical engineering services in the ministry of health
- Health technology management
- Health care technology manager for secondary hospitals
- Hospital engineer
- Hospital medical equipment management and repair
- HTM advisor
- Manage equipment in my province
- Medical support manager (provincial general hospital)
- Specialist in disability and assistive services
- Technical advisor at ministry level

Administrative or Planning

- Advisor in health care delivery programs
- Advisor to hospital management
- Advisor to provincial directorate of health
- Consultant
- Decision maker
- Draft health-related policies and plans
- Head of planning division
- Health economist planning health services
- Health system consultant

- Manage health laboratory services at the ministry of health
- Manage health care technology for country
- Management of health technology in ministry of health
- Manager in radiography
- Planner
- Provincial health care manager
- Provincial manager of public health

Conclusions

Faculty, participants, and organizers considered the Advanced Health Technology Management Workshop to be a success. Workshop evaluations indicated overall satisfaction with both the content and the method of delivery. Areas of improvement were identified that will be incorporated in future Advanced Clinical Engineering Workshops. Impact evaluations with the participants at some point after the workshop are useful to determine whether the information from this workshop made a difference in health technology management in the participants' respective countries. The Cape Town AHTM Workshop serves as a model for future health technology management workshops presented for developing nations.

Distance Education

James O. Wear
Veterans Administration
North Little Rock, AR

Alan Levenson
MediqPRN
Pennsauken, NJ

Distance education is not new. It has been around for decades, but recently it has received more publicity with the advent of the Internet. The first distance-education courses were correspondence courses, back before the turn of the 20th century.

With the reduction in hospital budgets, continuing education is becoming more difficult for clinical engineers (CEs) and biomedical engineering technicians (BMETs) to obtain. Education costs for all staff are being reduced because they are not easily charged back to patient care. At the same time, CEs and BMETs are required to have continuing-education credits (CECs) to maintain their certifications or licenses as professional engineers. Distance education provides an economical way to obtain this continuing education.

Many electronic technicians were trained with extensive correspondence courses in general electronics or radio and television repair. When introduced 40 years ago, audio teleconferencing became a useful adjunct to distance education. In audio teleconferencing, lectures are presented over a telephone, and students are able to ask questions. A dialogue between instructor and student can occur. Another form of distance education has

been the use of videotapes and audiotapes, where lectures have been put on videotape or audiotape. With the addition of written material and an exam, while not interactive, this distance education program is an enhancement over textbook correspondence courses. The introduction of video teleconferencing was yet another improvement in distance education; lectures could be seen, not just heard. Video teleconferencing is an enhancement over a videotape in that the presentation is live and, in some cases, two-way video technology can render the teleconference interactive. Correspondence courses changed with the advent of computer technology. These computer-based courses are simply correspondence courses utilizing computers. While actually similar to some of the correspondence program instruction courses, computer-based courses are more interactive.

The Internet and courses on the World Wide Web can be interactive. Frequently, some of these courses that have been computer-based or videotaped are now placed on the web so that they are available at any time. Interactivity can be added to these courses. With the advent of all of the new technology and the interest in distance education, degrees can be offered either partially or entirely by distance education.

Correspondence Courses

Correspondence courses have been popular for generations. The enrollee can study, do exercises, and take tests at a remote site of convenience. Educational material, typically textbooks or lecture notes, is sent to the student by way of the US Postal Service or common carrier. Upon their completion, assignments and exercises are sent in for grading. Generally, one examination is given at the end of the course. In some programs, the examination is monitored, or taken at a school, library, or other remote location. If the program is considered a self-study program, it might have a self-administered examination, which is then returned to the program for grading.

College credit is given for correspondence courses offered by many colleges and universities. One can complete general education requirements for an associate's or baccalaureate degree by this method. The completion rate for these programs is 40%–50%.

Some schools provide only correspondence-course programs. These schools typically bestow certificates of successful completion of a course and, in some cases, offer courses for which the student can receive college credit. Over the years, various electronics programs have been instituted in this way. These have extensive correspondence courses, including physical experiments. These programs have been accredited, and program expenses can be covered by the GI Bill. Many programs were established after World War II and trained people for radio and television repair. Some of these courses include the actual construction of a radio or a TV, or, more recently, a computer. Most of these courses originated after World War II as a result of the GI Bill passed by Congress and signed by President Franklin D. Roosevelt to provide benefits for soldiers returning from conflict. The United States GI Bill Act of June 22, 1944 (NWCTB-11-LAWS-PI159E6-PL78 (346)) put higher education within the reach of millions of veterans of World War II and later military conflicts. Veterans' benefits could be used for these courses if they met certain standards. As technology changes, correspondence schools change as well. They now feature such subjects as computer repair and communications networks.

The International Correspondence School has been in business for many years and has offered a variety of subjects by correspondence. It is now known as Thomson Education Direct. (See www.educationdirect.com.) TPC Training Systems (www.tpctraining.com) has a variety of courses that can be used by an institution as correspondence courses, with TPC grading the exams. Scientific Enterprises, Inc. (www.scientificenterprises.com) has a large number of self-study courses in biomedical engineering, hospital engineering, and hospital safety.

In addition to companies, several government agencies have developed their own correspondence programs. The Department of Veterans Affairs has had an extensive correspondence program for over 30 years for hospital engineering and biomedical engineering. The military as well has had extensive correspondence programs over the years.

Some correspondence programs have gone through transitions from strictly textual material to self-paced material, which was partially interactive and allowed people to go through a study activity at their own pace. Computer-based instruction is now available in which the text material and video clips are put on CD-ROMs. Exams can be given at particular places throughout the course. By these means, the material is interactive. If a question is missed, the program can refer the student back to the section for restudy. Prior to the CD-ROM, some of these programs were available on floppy disks, but they did not have the capability or as much of the interactivity of video clips because of the medium's insufficient storage capacity.

Audio Teleconferences

Audio teleconferencing, which has been in existence for decades, remains a viable teaching modality. The two main programs in clinical engineering, which have been in existence for several years, are sponsored by the Department of Veterans Affairs (DVA) and the American College of Clinical Engineering (ACCE). (See Chapter 130.)

An audio teleconference is a relatively inexpensive form of distance education that can provide many participants with the same information. It does not require any sophisticated equipment except the bridge that connects the phone lines. In the United States, commercial sites can furnish the bridges and phone lines for less than \$25 per hour per site. All that is required by the speaker and the participants is a speaker phone with a mute button. The audiovisual support can be provided either by handout materials or by slides, transparencies, computer files such as PowerPoint® presentations, or even videos that can be shown at the local site.

A facilitator is desirable at each site with half a dozen or more participants, in order to encourage maximum interaction. This allows for local discussion and the possibility of workshop exercises. It is possible to go offline in the course of a presentation to conduct a workshop or discussions, or to watch a video, and then to go back online for discussions with the speaker.

In order to achieve maximum interaction, having no more than 50 sites online at a time is advisable. The number of participants at a site can be as few as one or as many as 20, with the most desirable number being between four and ten. Enough participants must be at a site in order to have some discussion, but too many participants make hearing or participation in the local discussion difficult, if not impossible.

The prime advantage of an audio teleconference is that the speaker can be at any site where he has access to a speaker phone; likewise, the participants can be anywhere as long as they have a speaker phone with a mute button. The mute button is critical to preventing noise and feedback over the lines. Another advantage of the audio teleconference is that it can be a series of conferences, rather than just one. Because two hours is about the maximum time that one can maintain the interest of a group, an extensive topic such as codes and standards is best presented with sessions extending over several days.

Department of Veterans Affairs Experience

The Department of Veterans Affairs (DVA) has been using teleconferencing for each distance education since 1974. Because the DVA has 172 hospitals, it typically does each audio teleconference four times, one for each of the four time zones of the contiguous 48 states. With this modality, the DVA can train 1000 or more biomedical engineering and safety staff on updates to codes and standards.

A committee of three clinical engineers develops the training material and serves as faculty. A pre-test, handouts, case studies, evaluation, and post-test are developed. A site facilitator is selected for each site. This facilitator must have some content knowledge and is usually the clinical engineer or a senior BMET. Before the teleconference training, there might be some benefit in a conference call with all of the facilitators, to discuss the procedures.

Case studies are developed from questions that are asked of the DVA clinical engineers in DVA headquarters. The participants at a site discuss these case studies, and they come to a consensus solution. The case studies are then discussed online with the faculty. At the end of the teleconference, each participant receives a copy of the correct solutions and the rationale.

The DVA has used this modality to teach people how to teach. Students watch videotapes and then come together to discuss what they have seen. They also make presentations between audio teleconferences and discuss their experiences, both successes and failures.

The DVA conducted a series of audio teleconferences to prepare people to take the clinical engineering certification exam (see Chapter 133). First, it surveyed the DVA clinical engineers to determine the topics that they needed to review. They arrived at the following topics: clinical laboratory, respiratory therapy, radiology, physical plant, and utilities. Then, the DVA education division located speakers for these topics and organized one or more audio teleconferences on each topic. Clinical staff and a clinical engineer presented each session. Most of the clinical staff speakers were not associated with the DVA but had experience teaching by audio teleconference. The faculty prepared handout materials, including audiovisuals, and provided appropriate reference articles. In the final session, the speaker was the chairman of the clinical engineering certification board, who reviewed the examination application form with the participants.

The DVA conducts a six-month follow-up evaluation of the effect of the audio teleconferences. These generally receive excellent ratings and demonstrate cost savings. The cost savings might be in the form of reduced maintenance time, better equipment evaluation, or canceled or reduced service contracts. Depending on the program, improved clinical customer response also might be an outcome. Of course, one outcome is the improved understanding of codes and standards as well as the survey process of the Joint Commission on Accreditation of Healthcare Organizations (JCAHO).

American College of Clinical Engineering Experience

In an effort to provide education opportunities for its members at a reasonable cost, the American College of Clinical Engineering initiated an annual series of audio teleconferences on clinical engineering topics in 1995. The format for these teleconferences is a 45-minute presentation followed by a 15-minute question-and-answer period. At least one week prior to the teleconference, the teleconference coordinator distributes handout material, including copies of computer-graphic presentations, at the participant sites. Participants complete evaluation forms on each session, and the University of Arkansas for Medical Sciences gives continuing education units to the participants.

The number of sites participating has varied from 10 to 20, with one to 10 people at each site. There have been 50 to 100 participants on each of the programs, and evaluations have been very good. The speakers receive modest honoraria. The sites have been charged \$125 per teleconference for up to four people, with an additional charge of \$10 per person. The teleconference series has been profitable for the American College of Clinical Engineering, providing funds that are used for further educational activities and ACCE member benefits.

Table 72-1 shows a list of some of the ACCE Audio Teleconference topics.

When the program first began, handout materials were mailed, but now these materials are typically sent to the participating sites electronically. At some sites, the PowerPoint® presentations are shown as the speaker talks. In any case, each participant receives a copy. The sessions are also recorded and are available for sale with a copy of the handouts. Copyright releases are obtained from the presenters for the material to be made available in this format.

Audio teleconferencing also has been used to teach courses for college credit in biomedical instrumentation technology. A program at the University of Arkansas for Medical Sciences has taught an introductory biomedical instrumentation course by audio teleconference. The lectures were presented for two hours each week. A student visited particular departments in hospitals to see and talk to the operators about equipment. In the following week, students could ask questions and discuss what they had seen. Codes-and-standards courses, including NFPA 99 and 101 and the JCAHO Environment of Care Standards, were also taught by audio teleconference.

Video Teleconferencing

The next highest level of distance education is videoconferencing or satellite broadcasts. Government agencies and commercial enterprises have used it often. Among the several technologies for audio and video communication that can be utilized are point-to-point high-speed phone lines or bridges to connect several points. This method is interactive and allows the instructor to see the participants and allows the participants to see each

What Is the Difference between CEs and BMET Managers?

other. Among the many systems available are V-Tel™ and PicTel™. Again, the bridge time can be rented from a third party (see Chapter 73).

Satellite presentations can be made through an uplink and then received at sites with a downlink, which is not too expensive. However, this does not allow any interaction except by a telephone call. True two-way interaction requires a full uplink at both ends of a program, which is very expensive. With the advent of digital systems, a good-quality satellite broadcast can be presented and picked up at the downlink sites. This gives a much higher quality presentation than has been possible in the past, but it still is only interactive through telephone calls.

The DVA has been using satellite broadcasts for their biomedical engineering and hospital safety programs. They have four studios around the U.S. with broadcast capability, and all of the 172 medical centers have downlinks for the digital signal. At the same time, the DVA has four full-time channels on a satellite. Broadcast programs are typically one to two hours and are presentations by individuals or panels. A toll-free number enables participants to call in with questions. However, as compared to an audio teleconference where people simply push a mute button for an open line, just the small effort in making a telephone call decreases interactivity. A satellite broadcast is a good way to present information, especially when participants need to visualize material rather than merely hear a lecture.

The next highest level of technology involves bringing the satellite broadcast down to the desktop, where it can be received through the network on personal computers. The DVA is currently installing this technology.

The Internet

Another area of distance education is the use of Internet and web sites. Universities are using this method to present material to students on campus, but it can be used to present material to anywhere that people have access to the necessary technology. (See Chapter 73.)

The Internet, with e-mail, can be utilized for teaching courses that might have been taught strictly by correspondence. This allows a student access to the instructor in a much shorter time frame than that which elapses in correspondence by letter. One additional advantage is that it is much less expensive than a telephone call. Exams can even be presented by e-mail. Web-based courses can actually be interactive and can include video clips. These can be useful, but they can be expensive to develop appropriately. A student must have a computer with a high-speed modem or some other rapid access to the Internet, to make efficient use of their time with a web-based course. Again, some of the web-based courses are used at universities or at hospitals on their local area networks. These networks typically have significantly increased transmission speeds. Because they can be taken at almost any time, web-based technology is particularly useful for short courses (e.g., code compliance) required for employees.

A web site's availability 24 hours per day, 7 days per week, is a significant advantage, enabling participants to work on courses at any time. The courses can be taken on demand, on the student's time, and not on the instructor's time. Because students can be from any country in the world, language barriers can increase the challenge for the instructor.

The one disadvantage of web-based courses is that they generally will not meet US Occupational Safety and Health Administration (OSHA) requirements as stand-alone programs. OSHA requires that training be localized, which means that one must have local names and phone numbers in the program. OSHA also requires that someone be present during the course at all times to answer questions. A question cannot be asked by way of e-mail, to be answered later. This means that if someone is taking a web-based course at 2:00 a.m., someone else must be reachable by telephone to answer a question. OSHA requires a great deal of hands-on training. Therefore, web-based courses are similar to those that utilize videotapes and that can be used in support of training, but they generally cannot be used exclusively. While the presence of someone who can answer questions can be arranged, the need for hands-on training remains a limitation of web-based courses.

Netmeeting, a specialized system that can be used over a network, allows all the participants to see the instructor's screen on their computers. This is useful for teaching the use of computer programs.

It is possible to obtain a college degree from accredited universities with a combination of residency and distance education. In some programs, a degree can be obtained without having to meet residency requirements. These programs can be composed entirely of distance education, including some online courses, experience credit, and company training. One must approach this area with caution, however, because some schools are accredited by regional accreditation agencies, and some are not.

Distance education has become a way of life for many professionals as technology, medical equipment, and the means of delivery of health care change. In order to keep abreast of key developments, CEs and BMETs must continue their educations. The only economical way to accomplish this is by distance education, which allows individuals to learn on their own time, at their own pace, at an affordable cost. Fortunately, the change in technology has also provided newer modalities with which distance education can be provided. Many find that, as adult learners, they can learn as much or more through distance education as they can in a traditional classroom on the college campus.

73

Emerging Technologies: Internet and Interactive Video Conferencing

Albert Lozano-Nieto

Assistant Professor of Engineering, The Pennsylvania State University, Wilkes-Barre Campus
Wilkes-Barre, PA

The main goal of clinical engineering academic programs is to train future professionals in the maintenance, repair, and overall management of clinical and medical instrumentation. The previous chapters in this section have discussed several academic approaches to clinical engineering education, either at a degree level or for continuing education.

The clinical engineering profession of today is undergoing major changes. Clinical engineers' main role is shifting from the traditional approach of performing preventive maintenance and repairs on equipment, toward management of technology in the whole health care system (Zambuto, 1997). The clinical engineers of today play a multifaceted role in the clinical environment as the result of their continuous and growing involvement with the management of clinical equipment. They regularly interact with the clinical staff, hospital administrators, vendors and manufacturers, clinical engineers at other facilities, and regulatory agencies.

It is in this constantly changing scenario that one must evaluate and modify approaches to the education and training of these future professionals. Educators must incorporate new and more efficient education techniques to keep students in consonance with the changes occurring in the industry. In the classrooms, they must anticipate the future needs of industry while maintaining the high levels of quality that traditionally have characterized clinical engineering education. Finally, educators must remember that employers demand not only a high level of technical skill from prospective employees, but also some experience in the clinical setting and teamwork and, especially, the outstanding communication skills that are so critical in the work environment (Xu et al, 1997).

The traditional components in clinical engineering education have consisted of lectures delivered by instructors and laboratory work focusing on troubleshooting and repairing diverse medical devices at the component and subsystem levels, as well as performing preventive maintenance tasks on the equipment. Lectures in the classroom address the basic principles of electricity and electronics, physiological transducers, the origin of biopotentials and biological signals, and the interaction between living tissues and electricity. The experimental portion in the laboratory normally is used to visualize the concepts previously developed in the classroom as well as stimulate the student's intellectual curiosity in areas that are not covered in lectures. Some academic programs also require students to successfully complete an internship in a health care institution, thus giving their graduates the opportunity to acquire experience in the workplace before graduating, which constitutes a definite asset to their future employers (Lozano, 1998). This approach is perfectly valid today inasmuch as students still need to know the basic working principles of medical equipment and need to be able to identify possible causes for its failure or malfunction, as the majority of in-house service calls are caused by operator error or erroneous equipment configuration (Westover, 1998). However, this approach is not enough by itself. Given the size and infrastructure of current academic programs in clinical engineering, the instructors alone cannot provide the breadth of perspective and in-depth coverage for all the issues that affect clinical engineering, from both a technical and a professional point of view. Furthermore, it is also widely recognized that educators will be able to increase their critical-thinking abilities and consequently become more effective once in the workplace by exposing future professionals to a variety of different opinions and points of view (Newport, 1997).

Clinical Engineering Education through Internet Resources

It is irrefutable that, in the last few years, different Internet services have played a major role in changing the ways in which one accesses, transmits, and shares information. These new resources can, and should, be used to improve the way one approaches the education of future clinical engineers, as the Internet and its related services constitute dynamic media with strong possibilities of continuous adaptation to the necessities of the user. Furthermore, the same platform supports a broad range of informational resources that was previously disseminated among a large number of locations and media. The Internet also makes available to the students information that traditionally has been difficult for them to obtain, such as the technical data on medical devices. The growing number of commercial

electronic medical equipment manufacturers that distribute their information through the Internet allows students to access quickly all of this information from the classroom. The Internet must be viewed as it was conceived: as a powerful and valuable tool to exchange ideas and information among individuals located at geographically distant points.

Developing Basic Skills Using Electronic Mail

Although virtually all of the students who are enrolled in academic programs in today's colleges and universities have computer accounts with Internet access, not all students will use them on their own initiative, nor will they explore the different and more complex possibilities that these resources offer. In the author's particular experience, e-mail was heavily used by the instructor to send and to review assignments and homework, as well as for other communication purposes. This exercise was based on a gradual approach of increasingly using more complex functions such as composing and editing, replying to the sender and to all other recipients, forwarding messages, sending attachments, and working with different fonts and layouts. The goal of this e-mail usage was to enable students to use e-mail, with all of its possibilities, on a regular basis.

Participating in Clinical Engineering Listservs

After the students become familiar with the use of e-mail, they are required to subscribe to a clinical engineering distribution list (or listserv). The primary goals of these distribution lists are to discuss and to share information among professionals working in the different areas relating to clinical engineering. Although the students do not feel comfortable enough to participate actively in the discussions, they gain important experience by reading the messages interchanged in the listserv. They feel as though they are a part of this professional group, learning not only about technical details of equipment, but also about their goals as professionals and the current problems and concerns that clinical engineers face today. This feeling of belonging to a distinct professional group is unique and cannot be achieved in the classroom, making this an invaluable experience. In addition, when the instructors are also monitoring the listserv, they can bring some of their current topics of discussion into the classroom. The author's personal experience shows that some of the most interesting discussions during the lectures were brought up by the students based on topics that were being discussed in the listserv. Table 73-1 lists some of the listservs carrying discussions that are interesting to the clinical engineering community. Because of the ephemeral life of some of these distribution lists, and their possible changes of electronic address, they should be considered only as examples, and readers are advised to search for an active list that meets their interests.

The World Wide Web as a Tool for Clinical Engineering Education

The World Wide Web (WWW) has become an indispensable resource for clinical engineering students to have closer contact with industry as well as a tool to search for employment opportunities. Almost all manufacturers, vendors, and distributors of medical equipment currently use the WWW as a vehicle to disseminate information about their products. Instructors in clinical engineering programs can use it by assigning work to the students in which they need to access and process this information, for example, asking students to conduct research on a particular medical device or to analyze the market characteristics and trends of specific equipment. The use of the WWW has tremendous advantages over the traditional media of distributing technical information, such as technical literature and brochures from manufacturers. These are costly items to produce and distribute, and they must be updated frequently as new models are introduced in the market. Manufacturers might then limit the distribution of these brochures to potential buyers, while the academic world might be overlooked. Even in those cases of good cooperation with academic programs, the delays between the requests for technical literature and delivery to the students could be too long to be incorporated effectively into the academic program. By posting all of this information on the WWW, manufacturers can update their catalog of products quickly and at a minimal cost, thus making it accessible to a wider audience. Students can access all of the information (from different manufacturers) that they need for their projects

TABLE 73-1 Clinical Engineering distribution lists

List Name	Address	Notes
BIOMEDTALK	listserv@listserv.aol.com	General discussions, mostly by US professionals. Average of about 20 messages per day.
BmList	lisproc@nor.com.au	International: Australian clinical engineering.
Cmbes	majordomo@clineng.sbr.manitoba.edu	International: Canadian professionals.
Electromedicina	electromedicina@valme.sas.junta-andalucia.es	International: For Spanish and Latin American clinical engineers. In Spanish.
SDbiomed	SDbiomed@yahoo.com	Regional: San Diego area.
biomedchat_Missouri	biomedchat_missouri@yahoo.com	Regional: Missouri area.
BMETs-Houston	BMETs-Houston@yahoo.com	Regional: Houston area.

from the classrooms, which allows clinical engineering instructors to incorporate these examples of industry uses into their academic curricula.

As the WWW technology evolves, fewer usage problems can be expected. Even though an Internet address (URL) is not permanent, the widespread use of custom domain names has solved the problem of having to remember complex URL addresses. Furthermore, these custom domain names offer an added warranty that the user need not know the address of the host where the information is stored, but only the URL for a particular manufacturer or distributor of equipment. The use of higher-bandwidth connections, even from homes, allows the possibility of incorporating stronger multimedia content without excessively increasing the amount of time needed to download a web page. This allows students to view, for example, realistic views of medical equipment, and to watch them in working action, and thus to increase the ways in which they assimilate this information. However, some of the old problems in using the WWW persist. Manufacturers of medical equipment do not acknowledge the existence of similar products from their competitors, leaving students without a complete and realistic understanding of the real market share of a specific manufacturer or the extent to which the claims of uniqueness of a particular technology made by manufacturers are shared by products from their competitors. One also must take into account that the vastness of the WWW (one of its great assets) can work against its best pedagogic use. Most of the students, especially in their first academic years, are used to working with only a limited number of resources and may feel overwhelmed by all of the possibilities of information offered on the WWW. Students also may experience problems finding and filtering information that is of interest to their projects if they are not completely familiar with the different search engines and searching strategies and the nonlinear structure of the WWW.

In addition to the technical information provided by the manufacturers and distributors of medical equipment on the WWW, the web pages from the clinical engineering departments of different hospitals offer the students a realistic view of the profession. Students and instructors can discuss the roles and mission of these departments, their structure, and the policies in use at specific facilities, and can take virtual tours of these departments to learn about the equipment that they service and the clinical staff with whom they must interact. Because the WWW is (mostly) not constricted by geographical boundaries, students also can compare ways in which different countries approach clinical engineering, and thus can get a broad vision of clinical engineering beyond what the educator might discuss in the classroom.

The WWW is also useful for introducing students to different professional organizations relating to clinical engineering. Clinical engineering instructors can use these organizations, whose URL addresses are shown in Table 73-2, as another tool to help students become closer to the reality of the profession and to understand the current issues and concerns in the field. For students who are about to graduate, the WWW has become an extremely important resource for seeking employment. Students can find job openings in different clinical engineering areas using the web pages from professional organizations, manufacturers, and independent service organizations as well as clinical engineering and biomedical engineering technology professional societies. Students can easily select the type of employment that they believe will best suit their personal preferences, while targeting specific geographic areas to which they would prefer to relocate. Faculty also can play a major role at this stage of the students' learning experience by discussing with them strategies for resume writing, interviewing, and negotiating compensation packages. In addition to these web pages, the previously discussed e-mail distribution lists also contain announcements of job openings at different levels, which contributes to an immersed learning experience.

Bridging the Gap Between Industry and Academia: Interactive Videoconferencing

Interactive videoconferencing is a useful and cost-effective way to bring students closer to clinical engineering professionals and industry. At the author's institution, interactive

videoconferencing is used in the Guest Lecture program, a series of presentations given to the students by professionals from the clinical engineering field for two hours per week during one semester. This series of lectures gives the students the opportunity to learn about the different kind of industries and employment opportunities that they might consider, as well as the opportunity to learn about the current important topics in the field. These lectures, which are summarized in Table 73-3, are balanced between those with highly technical content, which gives the student an in-depth view of a specific piece of medical instrumentation, and those aimed at providing them with a breadth of perspective on the profession. The technical lectures describe in great detail the technical and functional aspects of different medical devices, basic working principles of which have already been covered in the classroom. Their purpose is to analyze the equipment in detail, taking into account its functional aspects and different operational modes. The breadth-of-perspective lectures focus on different aspects of clinical engineering that traditionally have been omitted from the formal curricular plans in academia but that will have a strong impact on their careers (Elder and Corrin, 1996).

Because the two campuses at Penn State that offer this degree are more than 300 miles apart, the guest speakers come to one of the campuses (normally the one closest to them), and their lectures are transmitted to the other campus by interactive videoconferencing. This technology allows for access to a higher number of students, while reducing the traveling costs and the inconveniences associated with traveling. The classrooms at both ends, where the lectures are originated or sent, are equipped with the necessary hardware to send and receive interactive videoconferences using a PicTel™ system. At the reception end, one TV screen shows the guest lecture being transmitted, while a second screen shows the image of the classroom that is sent to the remote end. This allows the interaction between the near-end students with the speaker. The speaker has a view of the local students, the remote-end students on the TV monitor, and a view of the signal sent to the remote end.

The assessment of this Guest Lecture program indicated that the majority of the students were satisfied with the program and that they welcomed the opportunity to interact with industry professionals. This analysis also showed that most of its perceived drawbacks were caused by the technology used. PicTel™ uses compressed video to limit the amount of information transmitted through the phone lines. The compression algorithm makes it so that, for example, fast movements in the near end appear non-continuous at the far end, and introduces a delay between both ends. This relatively small delay (around two seconds) can appear significantly long to the students at the remote end. For example, when one of these students asked a question of the guest lecturers, he had to wait two seconds until the lecturer acknowledged this question. Because the students are used to interacting with live instructors, this delay is erroneously perceived as the guest lecturer not paying attention to the students at the remote end. Once the students at the remote end become used to the specifics of this technology, they become more comfortable and interact at a higher level with the speakers after only a few lectures.

Figure 73-1 summarizes the major benefits, as selected by the students at the remote end, resulting from incorporating the Guest Lecture series into the clinical engineering program. The students positively valued the possibility of acquiring more in-depth technical information on specific medical devices, as well as the interaction with professionals who are currently working in the field. Although all the students indicated that the program was well balanced between technical lectures and more general lectures, almost all of them showed a preference for the technical lectures, as compared to the breadth-of-perspective lectures. This last result is not surprising, as these students have chosen to

TABLE 73-3 In-depth and breadth-of-perspective guest lectures delivered by interactive videoconferencing

Guest Lecture Program Contents	
In-Depth Technical Lectures	Breadth-Of-Perspective Lectures
Career opportunities in clinical engineering	Consequences of ineffective technical writing
Defibrillation technology	Preparing effective resumes
Clinical practice of electrosurgical unit	Interviewing and job prospects
Vital signs monitoring	Independent service organizations (ISOs) opportunities
Y2K issues in health care	Writing business letters
Blood borne pathogens – universal precautions	Developing customer relations skills
Patient lead wires	OSHA regulation: lockout/tagout procedures
Introduction to radiology	BMET and CE relationships with other health care professionals
Introduction to anesthesia gas machines	Medical device investigation

JCAHO	http://www.jcaho.org/	Joint Commission on Accreditation of Healthcare Organizations

- A. In-depth understanding of medical instrumentation
- B. Interaction with industry professionals
- C. Introduction of new equipment to students
- D. Dialog with clinical engineering professionals
- E. Introduction of new topics

Figure 73-1 Summary of benefits from the Guest Lecture program as perceived by students at the remote end.

- A. Lecture was balanced between information and technical content
- B. Speaker had a good sense of humor
- C. Speaker had good communication skills and used good audiovisual aids
- D. The equipment under discussion was very interesting

Figure 73-2 Summary of good characteristics of interactive videoconference lecturers as perceived by students at the remote end.

pursue careers in a specialized and highly technical field. The major problem identified by the remote-end students was the lack of human interaction between the guest speaker and themselves. Human contact and personal interaction still is perceived as the single most important aspect of education. In this context, the speaker's personality, the interaction with both groups of students, the careful use of audiovisual tools, and especially the realization that there are two groups of students with different needs become critical to ensuring that the audience at the remote end is reached successfully.

Figure 73-2 summarizes the characteristics that made the most interesting lectures, as perceived by the students at the remote site. Figure 73-2 shows that the speaker's personality (in particular, their enthusiasm and interest in involving their audience in the topic being discussed and creating a relaxing atmosphere) is valued as one of the most critical parameters for a successful lecture. The students also positively valued loud and clear speaking, as well as the effective use of audiovisual aids. These characteristics are not new, as they are known by those who routinely speak before audiences. However, they become critical during videoconferencing because all of the other communication channels that one has with a near-site audience are absent, and they become the only human contact between the speaker and the remote audience.

Conclusions

The new goals and approaches in clinical engineering education, which are needed in order to keep up with the ever-changing professional scenario, demand the use of new technological tools that, combined with the traditional tools and approaches, can bring a new dimension to clinical engineering education, creating a learner-centered approach. This learner-centered approach shifts the traditional paradigm of instructor-to-student information delivery to one of making the students the center of their educational experience. Internet tools, as well as videoconferencing, are two of the different techniques that can be used in conjunction with more traditional approaches, to increase learning experiences and to better educate future clinical engineers.

The different Internet services constitute an exciting and promising aid in a clinical engineering educational program to enhance the students' learning experience. These tools provide a vast array of resources to complement what the students have learned during the traditional lectures and laboratory experiences. Professional distribution lists also play a unique role in enhancing their education. These lists open a window to the professional field of clinical engineering while the students are still in school, giving them the opportunity to have a sense of belonging to a distinct professional group while learning about their problems, rewards, and other issues that clinical engineers face daily. The wise incorporation of some Internet services in a clinical engineering curriculum will enhance their learning experience and will prepare them to become better professionals.

Another emerging technology with a bright future for clinical engineering education is the use of interactive videoconferencing. This approach brings industry into the classroom, allowing students to become closer to the different facets of clinical engineering. The students who have participated in the Guest Lecture program at Penn State University

have recognized this fact as the most important outcome of this program. Students also have recognized that despite their preference for a certain type of lecture, there is a need to be well-versed in all of the areas that may pertain to clinical engineering. Clinical engineering educators can help students to understand this need by stressing from the beginning of the program the need for future professionals to acquire a breadth of exposure to all of these areas, which will play major roles in their future career development and possibilities for advancement as clinical engineers (Kearney, 1996).

The use of these technological tools is not exempt from potential risks. The dynamic media and the immense capacity for information storage and retrieval that drives the Internet resources can become their major drawback if faculty do not carefully design its use as an educational tool. The benefits of the use of videoconferencing systems can be reduced by the absence of human contact between the speaker and the students, as the technology does not allow all of the communication modes of face-to-face lectures. Given these limitations in communication modes, the personality and skills of the speaker to reach the remote audience become critical to ensuring that students at the remote end obtain the most benefits from the videoconference. Prospective distance speakers need to evaluate their communication techniques and to realize that the students at the remote end will see them only through a television screen. These speakers must pay constant attention to the remote-end students who are trying to engage them in interactive discussions during the entire session, in order to have a productive atmosphere.

The use of Internet resources and videoconferencing with industry professionals can become excellent tools for clinical engineering educators, as they bring students closer to the reality of the profession. Like the introduction of any other tools in the classroom, they require an adaptation period in which instructors and students need to work together and explore the ways in which these tools can be used in order to obtain the maximum benefits (Lozano, 1998b). Undoubtedly, all of these new approaches impose additional burdens on the faculty, as they must create new ways of instruction, delivery, and experimentation with these tools. However, the positive effects that these methods will have on the professional performance of graduates clearly counterbalance any inconveniences. With the aid of these technologies, clinical engineering faculty will be able to develop newer academic approaches, moving toward a learner-centered paradigm. This will allow students to be immersed in the reality of the profession at an earlier stage and, consequently, to become more interested and involved in the clinical engineering academic program, thus working synergistically to produce better professionals.

Summary

New technologies, particularly the use of Internet resources and interactive videoconferencing, can become extremely important educational tools for academic programs in clinical engineering. The roles and responsibilities of clinical engineers are undergoing major changes that must be reflected in the way that future professionals are being trained. The Internet, with its vast array of resources, can be used effectively by faculty in these programs to bring industry closer to the students. Students can use Internet resources to

examine and to analyze products from the manufacturers and distributors of clinical and medical equipment. Student participation in professional distribution lists that focus on clinical engineering issues will give them insight into the current issues and problems in the profession. The use of interactive videoconferencing in the classroom is another tool that can increase the connection between students and current industry professionals. All of these resources will contribute to providing current clinical engineering students with a broader view and understanding of the clinical engineering profession.

In-Service Education

James O. Wear
Veterans Administration
North Little Rock, AR

One important role in a clinical engineering department in a hospital is to provide in-service education for the clinical staff (Dyro, 1988). The Joint Commission on Accreditation of Healthcare Organizations (JCAHO) requires continuing education for all of the hospital staff, especially in the clinical areas (see Chapter 58). This continuing education ensures that the staff maintains competency, and it helps to reduce errors and to improve patient safety.

In-Service Topics

The clinical engineering staff is in the best position to provide in-service education on topics that relate to medical equipment and to certain areas of safety. In addition to maintaining medical equipment, the clinical engineering staff should be aware of the way the equipment operates; therefore, the staff is frequently in the best position to teach people the proper use of equipment as well as any required operator maintenance. All employees must be particularly aware of the JCAHO Environment of Care standards and the medical equipment management plan, in particular. The clinical engineering department should be responsible for providing in-service training on the implementation of the medical equipment management plan to the clinical staff. Despite the fact that the electrical safety concern—one of the cornerstones upon which clinical engineering was built—has been exaggerated and is but a small part of the clinical engineer's concern (see Chapter 65), it is nevertheless advisable that the clinical staff receive electrical safety in-service training. Electrical safety remains a part of the patient safety program and remains a concern of individual employees.

Below is an outline for a typical electrical safety program for nursing personnel. Its elements should be in any course outline. The objectives of any training activity must be well defined and articulated, as they serve to keep the presentation focused. The outline, which includes the objectives, provides a direction for the presentation and lets the participants know what will be covered.

When to Conduct In-Service Training

One could say that any time is the right time to conduct in-service training, but there are times when it definitely must be provided. When new equipment arrives, there must be in-service training for the operators. If the vendor is providing this training, then the clinical engineering staff also should receive this training because they need to know how to operate the equipment that they are going to maintain. Clinical engineering staff will pro-

vide future in-service training on the equipment. The initial in-service training is critical to ensuring that the clinical staff understand how to properly use the equipment; this understanding can reduce, if not eliminate, operator error, a major factor in medical device related incidents and accidents (see Chapter 55). Thus, in-service is a fundamental component of a hospital safety program (see Chapter 58).

In-service training must be conducted for new users who are unfamiliar with the operating characteristics of a device. If the turnover rate of the clinical staff using the equipment is high, the in-service training burden increases, especially in a teaching institution where students and interns who might be using the equipment come and go with regularity. Frequently, the service in which the device is used will have knowledgeable users who are capable of providing in-service training. These services might depend on the clinical engineering staff to provide some parts of the training, however. Clinical engineering staff should welcome the opportunity to be part of the in-service training team, because knowledgeable users lead to increased patient safety and a low level of maintenance associated with user error.

When a pattern of user errors is identified, in-service training can be one way to reduce the incident of errors. The clinical engineering staff, with the aid of such tools as a computerized maintenance management system (see Chapter 36) is often in the best position to identify patterns of user error. One indicator of the need for training is a pattern of frequent calls for medical device maintenance in which no problem is found. This typically means that the users do not know how to use the equipment properly. Another symptom of user error is the recurrence of a particular maintenance problem for which there does not appear to be any explanation. Obvious equipment abuse or misuse indicates the need for in-service training. The general maintenance record on a medical device can suggest user error. User error should be considered whenever a device has a higher than expected frequency of service.

In-service training where user error is involved should be conducted in a sensitive manner so as not to polarize nursing and clinical engineering (Dyro, 1983). The user generally does not want to admit that he does not know how to use a medical device properly. This in-service training could be no more than just reinforcing for the doctor, nurse, or technician ways to use the equipment, and what might have caused an equipment failure. If conducted properly, training is accomplished without the operator losing face. In a more serious situation, such as accident investigation (see Chapter 64), the clinical engineering department might need to discuss with the supervisor of the using department the need for in-service training. In any case, the training must be done in a positive manner and must not place blame on the user for improperly utilizing the equipment.

Table 74-2 lists the considerations that the clinical engineering staff should use in establishing an in-service training program. These can be used to develop a single presentation, a series of presentations, or a complete training curriculum.

Table 74-1 In-service outline for electrical safety for nursing

Objectives:

1. Nursing staff will understand basic electrical concepts.
 2. Nursing staff will be able to distinguish between microshock and macroshock.
 3. Nursing staff will be able to discuss leakage current.
- I. Basic electricity
 - a. DC electricity
 - b. AC electricity
 - c. Ohm's law
 - II. Electricity in the hospital
 - III. The patient as an electrical conductor.
 - IV. Macroshock vs. microshock
 - V. Leakage current
 - VI. Electrical safety policy
 - VII. Electrical safety testing

Table 74-2 Considerations for a training program

- I. Why Have a Training Program?
 - A. Employees are unable to do something.
 - B. Employees are unable to do something well enough.
 - C. Employees are doing something wrong.
- II. Prerequisites For a Training Program
 - A. Determine knowledge requirements.
 - B. Determine skills requirements.
 - C. Appraise individual capabilities.
 - D. Decide on training methods to be used.
 - E. Investigate availability of appropriate training materials.
 - F. Establish proper environmental conditions for training.
- III. Objectives of a Training Program
 - A. Provide the knowledge and skills needed.
 - B. Provide knowledge that is relevant to work experience.
 - C. Provide continuing education opportunities.
 - D. Encourage individual effort.
 - E. Remain flexible to suit varying work situations in your hospital.
- IV. Questions to Be Answered Prior to Start of Training
 - A. What will be the size of the training group?
 - B. How frequently will sessions be held?
 - C. What should be the length of each training session?
 - D. Where will the training sessions be located?
 - E. What time of day are study sessions to be scheduled?
 - F. What are the objectives of the program?
- V. Establishment of Administrative Guidelines
 - A. Method of selecting trainees
 - B. Specific schedule for training
 - C. Scheduling work experience
 - D. Reviewing or testing of the trainees' progress
 - E. Certificates of completion, or formal recognition at the completion of training
- VI. Review Points for Evaluation of the Training Program
 - A. Make the evaluation an integral part of the training program.
 - B. Let trainers and trainees know the evaluation methods and standards.
 - C. Were objectives met?
 - D. Was the training valid?
 - E. Were the mode of the instruction and the administration of the program satisfactory?
 - F. Determine trainee behavioral change—job satisfaction.
 - F. Base evaluation on demonstrated performance.

How to Train

Training can be accomplished in many different ways, and the modality that is used will depend upon the trainer as well as upon the participants. The method used will also depend on whether someone is trying to teach cognitive material or skills. In Table 74-3 are some important things that a trainer should consider, to create a good learning environment for trainees. These are some of the basics of adult learning:

One method of training is by discussion—an informal method that can be a one-on-one discussion or with a small group. This method allows for the greatest amount of interaction between the instructor and the learners. In many cases, this is the least threatening training tool and is useful to train someone when training is needed. For example, when a clinical engineer (CE) or biomedical equipment technician (BMET) sees a user improperly using a medical device, proper operation can be discussed, and demonstrations made. The user is in a highly receptive mode at this point, and the chance of learning and retention is enhanced as a consequence. One could call this method “just-in-time learning.”

The classical method of training is the lecture. It is particularly good for teaching groups of people cognitive material. It is a more formal method of teaching and requires time to prepare handouts, audiovisuals, and other support material. Typically, two or three hours outside of the lecture are required to prepare a one-hour lecture. For a lecture to be appropriately presented, the instructor must find ways to hold the attention of the learners. If possible, the instructor must get the learners involved with some interaction. This involvement becomes more difficult with a larger class.

Table 74-3 Some important things that a trainer needs to do to help trainees learn

1. Learners control learning; instructors control teaching.
2. Learning might not result from teaching.
3. Motivating learners is the first task of instructors (trainers).
4. Information to be learned must be organized logically.
5. Teaching must provide for learner participation response and experience.
6. Organize detail into structured patterns to increase memory retention.
7. The way a learner feels influences his or her ability to learn.
8. Learning is a perceived change in behavior.
9. Behaving and learning are products of perceiving.
10. Practice, alone, is not adequate for learning to occur.
11. Retention increases when learners can self-correct their work.
12. Varying the teaching methods improves learning.
13. Information to be learned must be presented to the learner at his or her level of sophistication.
14. Learning is increased when new information is presented in a fashion that closely simulates the real world.

One important form of in-service education is the demonstration. Because much of the in-service education provided by the clinical engineering department is the proper use of medical equipment, this is best taught by demonstrating usage. This training is actually performed where the equipment is used and may be done for one or several learners. This technique is utilized when someone is found to be misusing a medical device. In order for the instructor to demonstrate the use of the equipment, he needs to know how to use it. The CE and the BMET need to know how to use the equipment they manage. It is also a good idea, when doing the demonstrations, to have a systematic job aid to leave with the learner.

Videotapes are frequently used as part of a training program. They never should be used as the only part of a training program. The keys to any training activity are the opportunity for the learner to ask questions, and for the instructor to be sure that the concepts being taught are learned. The videotape might do an excellent job of the presentation, but it does not allow for any interaction or feedback. It can be shown and then discussed with the participants. One good technique is to use a series of short questions that cover the highlights of the videotape as a self-graded quiz. Then, the answers to the questions can be discussed. This actually provides a significant amount of reinforcement of the concepts that are being taught.

A slide and audio tape or a computerized slide presentation using such software as PowerPoint® can be used as part of a lecture presentation. Students can view the presentation on their own. However, as in the caution given concerning learning by watching videotapes, the presentation is not sufficient on its own. A well designed slide presentation can be used effectively as a support for training. Participants can go through it, take a quiz, and then discuss the material. It is possible that the discussion arising from either a computerized slide show or a videotape could occur later.

Modalities such as CD-ROMs or web-based training can be utilized, but these are typically a mix of PowerPoint® slides or video clips (see Chapter 73). If well done, they can provide some participant interaction. However, for the most effective training, the learner must have the opportunity to ask questions and to discuss the material with the instructor. With some training, such as that required by OSHA, there is a requirement that there be the opportunity at the time of the training for the participant to ask questions. This can be satisfied by having someone be available by telephone.

An examination is an important training tool. Unfortunately, most people look at an exam as a threatening situation, especially adults who have been out of school for many years. However, the exam can be used in a nonthreatening manner and does provide assurance that someone has gained some knowledge or has learned a skill. An examination can entail writing answers in response to specific questions, demonstrating the proper use of a medical device, or both. These methods provide reinforcement to the learner, who must recall the information that has been presented. Discussing the exam and the correct answers thus becomes another method of reinforcement. In general, the exam need not be graded. However, it is important for the instructor to have some feedback, in order to know whether the learners are able to recall the material presented.

In an exam in which an individual must demonstrate how to use the equipment, only a passing or failing grade is possible. It is unacceptable and unsafe for medical personnel to know how to use the equipment only 70% of the time, or to know how to use only 70% of the features. They either must know how to use the equipment or not use the equipment. This would be like having a pilot of an aircraft know how to take off, but not how to land.

All of these training techniques are in the instructor's toolbox, and many times they are used in combination with each other. The instructor must determine the best training modality for the material presented and for the type of learners being taught.

Lecture Improvement

For in-service education and training, the lecture is probably the modality that is used most of the time. Videotapes and computers might support the lecture. A discussion is really a form of lecture. Even though it is informal, it should have some of the elements of a lecture. The lecture is prepared with an outline like the example in Table 74-1 and with the considerations listed in Table 74-3. Table 74-4 lists ways to present effective lectures. One must be flexible with the presentation and must use feedback. Students become bored quickly if they already understand the material being presented. Watching the students provides feedback. Bored expressions, wandering eyes, fidgeting, doodling, and yawning are all signs that one might be able to move on to new material that would bet-

Table 74-4 Guidelines for an effective lecture

1. Do not attempt to teach too much material.
2. Focus on student performance instead of on your own.
3. Tell students your objective.
4. Tell students why the objective is important to them.
5. Make your talk personal.
6. Begin with simple, basic, or familiar tasks and move to complex, sophisticated, or unfamiliar information.
7. Break the material into short sections:
 - Ask questions.
 - Ask for judgments.
 - Let them know whether they were successful.
8. Change the pace—stop often, get feedback, and give feedback.
9. Use visual images and concrete aids whenever you can.
10. Find out how effective you were at the end, with a short post-test.
11. Ask your students to evaluate your lecture anonymously by answering interview-type questions.
12. Analyze the data you receive from the post-test and interview questions.

ter hold their interest. This will allow the instructor to meet the objectives of learning new skills and concepts. One should not be surprised if a one-hour lecture is completed in 30 minutes. On the other hand, one may find that the lecture material was above students' knowledge and skill base. In this case, additional remedial material must be covered. Extending an in-service lecture is not advisable, however, because the participants must return to their jobs. Should remedial material be added, it is preferable to cut some of the prepared material, thus ensuring timely completion and maximum comprehension.

Take time to make good visuals, such as slides, overheads, or computer graphics. A good presentation can be wasted with poor visuals. The visuals should enhance

the presentation, not diminish it. The following are guidelines for creating effective slides:

1. Use horizontal format.
2. Keep text and graphics within a safe central area.
3. Use big, bold lettering, 24-point or larger.
4. Use only six lines per slide.
5. Use only six words per line.
6. Check for readability. (If displayed on a 17-inch monitor, can it be read at 17 feet?)
7. Do not use vertical lettering.
8. Present one main idea per slide.
9. Keep the focus on key points.
10. Keep the text simple.
11. Illustrate difficult concepts.
12. Use visuals to enhance text.
13. Do not use fancy backgrounds.
14. Use contrasting colors.

Knowledge Transfer

We need to transfer information and knowledge from subject-matter experts to others, to continuously maintain and expand the body of available knowledge. In the traditional, formal education system, the "taking of students from the known to the unknown" has been performed by the "talking head" method. Students sit in a classroom and listen intently while the teacher makes the presentation. Sometimes training aids are used, but the information transfer is accomplished via the talking head at the front of the room. This method has many limitations, such as the expertise of the educator, presentation skills, limited audience, time constraints, and varying student learning abilities.

Early "distance education" methods continued to use the talking head in videotape or slides. Often, the educator was not visible, and the student saw the training aids most of the time. With the widespread availability of computers, the Internet, and the World Wide Web, present-day distance education has proliferated in all aspects of education and training.

We should point out that there is a difference between education and training. Education is broad in scope, general in nature, and intended to provide a basis for future application of the knowledge. As an example, think of the study of the production of X-rays in machines without application. Training is focused on a particular topic and is intended to provide the student with specific information regarding a task; for example, the way that a particular machine generates X-rays, or the requirements for keeping that machine in proper working order.

Distance-education techniques, specialized education software, and advanced delivery techniques have allowed educators to reach many more individuals. Training and education packages cover a myriad of topics to varying degrees of complexity, functionality,

cost, and usefulness. The more familiar the student is with the subject matter, the better the chance that the package will be useful. One unfortunate effect of the ease of development and distribution of distance education is that some packages are full of "fluff," without much "meat." Some packages are nothing more than a book on a CD, without any real curriculum.

Another concern with "training packages" is that the information is presented in only one way, and no matter how many times you view it, it still says the same thing, the same way. Still another concern is that you cannot ask the package questions for clarification or understanding. Some packages will provide for some type of feedback from the student and even a forum for communication with other students and the subject-matter expert. More sophisticated, and expensive, packages contain checkpoints, quizzes, and examinations to ascertain the level of knowledge transfer.

So, is the talking head *dead*? Many feel that most education issues, and even some training issues, can be adequately addressed using distance education and training packages. Some examples are the way X-rays are generated within the X-ray tube, the way the Doppler effect is used in ultrasound, the purpose of a flood in nuclear medicine, and the way a gradient affects the MRI magnetic field. These types of knowledge do not really require the presence of the subject-matter expert or even a machine. With the proper design and delivery, a training package could present the requisite information for understanding of the concept involved. This type of knowledge is relatively easy to transfer with a package because it involves a type of memorization. The actual installation, calibration, and optimization of an X-ray tube are different matters, however.

It is appropriate here to speak of the ways in which people learn. Some people are visual learners—they learn more easily when they can see the subject matter. Others are aural learners—they learn better by hearing. The third group is kinesthetic learners—the

doers, the hands-on learners. In the attempt to take people from the known to the unknown, the curriculum developer/presenter must take into consideration the particular learning characteristics of the target audience.

Our dilemma as trainers is to choose the appropriate curriculum and delivery method for the subject matter and the learner. In diagnostic imaging service training, the student is more likely to be a hands-on type of learner. Their choice of profession, and our extensive experience in training them, clearly punctuates this. Add to this the inescapable and inherent danger in servicing high-voltage, radiation-producing machines, and we come to the conclusion that a student should have live access to the machine.

The access must comprise controlled and supervised laboratory exercises and troubleshooting lessons as well as checkpoints, quizzes, exams, and the timely critique of individual progress. The student must develop a strong respect for, and the appropriate fear of, the dangers presented by these types of systems. These components of the training process cannot be provided by a distance-training package that is developed and delivered by present technology. The subject-matter expert must be available to ensure maximum transfer of knowledge and to observe the learning process. Because learning is "a relatively permanent change in behavior," the student must be monitored for the requisite behavioral pattern. The proper and efficient maintenance of these complex and dangerous machines requires a behavioral process that is best provided and supervised by the expert "talking head."

A quality curriculum design and presentation expert will provide the student with the greatest opportunity to acquire the requisite behavioral skills to fully service complex and dangerous equipment. One often-made mistake is that an organization will ask the local "service expert" to provide on-the-job training to coworkers in an attempt to save training dollars. Knowing a system does not equate to having the capabilities to teach the system properly. Good talking heads don't grow on trees.

Quality education and training of complex and dangerous equipment such as diagnostic imaging systems requires the proper mix of expertise, knowledge, curriculum design, delivery method, checkpoints, quizzes, exam, hands-on laboratory and troubleshooting exercises, instructor and student critiques and follow-ups, and, yes, a "talking head."

Training Sessions

DITEC is one of several organizations that provide training and other educational opportunities such as conferences, seminars, and publication primarily in the field of high-tech medical technologies. DITEC presents training sessions throughout the year on diagnostic imaging service and management training. Figure 75-1 is a typical schedule of programs. Modules are presented from two to seven times annually. Participants travel to the DITEC training facilities in Solon, Ohio. DITEC also takes its modules to groups throughout the United States. For example, in 2003, a program on diagnostic radiology systems was presented for the members of the New England Society of Clinical Engineering. (See Chapter 131.)

Diagnostic Imaging Continuing Education Conference

For a decade, DITEC has sponsored an annual Diagnostic Imaging Continuing Education Conference. Conference sessions typically include the following areas:

- Management
- Multivendor service
- New technology
- Regulatory and performance
- Professional development

The following is a list of the courses presented at one of these conferences.

Financial Management for Clinical Engineering

In today's environment, an understanding of financial reports, accounting systems, and reimbursements for services is important to all managers. Clinical engineering managers must have a clear understanding of the ways in which these systems work, to be able to make informed decisions on capital and operating budget development and analysis, equipment selection, variance analysis, future and present values of money, cost analysis, and other functions.

The True Cost of Lowest Price: Thinking Beyond the Current Budget

Managers often are faced with such rigid budget constraints that they are unable to think past their current budget. The focus should be on the price/cost relationship, and understanding that a lower price may mean much higher cost over the asset's lifetime, and significantly higher over the institution's life. Dynamic asset management must take many factors into account in order to provide an institution with the best solution.

Equipment Planning: Sanity vs. the Lost Opportunity

Come and see how you can develop and execute a comprehensive Equipment Planning Strategy addressing these critical components: Health care technology, capital budget, strategies procurement/installation coordination, equipment application vs. technology advancement, and building interdepartmental relations. Understand the approach for the simple process of planning current and future capital equipment expenditures.

Image Systems—Upgrades Without Fear

This session will cover interfacing and servicing the ideal CCD Camera and Image Processor combination, the technical aspects of the host equipment requirements, image intensifiers, optics, and pulsed fluoroscopy. The applications covered are for R/F, DSA, and Cine. With flat panels, image intensifiers, optics, CCD Cameras, PC-based image processors, how do I make sure my investment will not be obsolete in a few years?

Increase Your Worth Through Effective Reporting

This presentation is designed to show how a department manager needs to keep senior management aware of the effectiveness of the department through various reports. Learn some of the "dos and don'ts" of reporting that will make your report show your best side and help gain the respect of your senior management and meet the requirements of the JCAHO.

Getting the Most Life from Your CT Tubes

Hospitals are dramatically cutting their overall operating costs of CT glassware by using the patented TLS Oil Process to extend tube life. Find out how this process works and why it *now* makes financial sense to put your expensive glassware on a regular PM schedule!

Marketing Yourself in the New Century

This seminar will discuss elements to consider when seeking employment or promotions in health care management, engineering, or a technical field. Emphasis will be on the professional growth value in a health care career path. Participants will learn marketing venues within the Internet and other resources, powerful resume formats that are best for today's fast-paced environment, proven successful interviewing techniques, and acceptable attire.

Who Moved My Cheese?

Change can be a blessing or a curse, depending on your perspective. Our lives and belief systems are mostly built around our "cheese"—our jobs, our career paths, the industries we work in. We have to be alert to changes in the cheese, and be prepared to go running off in search of new sources of cheese when the cheese we have run out. This session will discuss some of the ways we can improve our "cheese."

Defining Your Performance Indicators

This session will discuss how members of the service profession can measure their service programs with tangible measuring tools. It will help establish guidelines for customer satisfaction up to the executive level. If your organization already has indicators, this session will help you improve them.

Spiral/Helical CT Scanners

The state of the art in CT scanning is called spiral/helical scanning. The session will cover this expanding and changing modality. The emphasis will be on the clinical and technical advantages of spiral/helical CT imaging and how it enhances 3D images.

Ten Common RF Studies

Good communications with the radiologist and the technologist requires a strong understanding of the RF studies routinely performed. This session will cover the 10 most common RF procedures, with an emphasis on the technologist's viewpoint. Positioning and technique selection required for good image quality will also be discussed.

FDA Regulations on ISO and In-House Servicers

This session will discuss the new responsibilities and accountabilities of ISO and in-house servicers of medical equipment under FDA guidance and enforcement. Practical methods of using the Code of Federal Regulations to improve safety, reduce costs, and eliminate restrictions on servicing medical devices will be thoroughly discussed. An exchange of questions and comments is encouraged.

In-House Technology Management

Health care managers face a wide variety of issues while trying to operate in an increasingly cost-containment-focused environment. In-house clinical/biomedical managers face even greater challenges with all the options and threats presented by others. This session will cover the options and resources a technology manager needs to be effective in today's health care market.

Flat Panel 2001—The Litmus Test

This session will provide an overview of the flat-panel imaging devices on the market and how they are holding up under the scrutiny of the critics. It will include the various application reviews and updates on future engineering projects and a prospectus of the new designs and the latest product developments by the industry leaders. Come prepared, and bring your best imaging questions.

Networking Today's Computers

This session begins with basic networks, their topology, and their cabling. This leads into a discussion of Ethernet and token ring technology, the ISO-OSI Model, TCP/IP, DICOM 3.0,

and network software. The key issue of DICOM Conformance is highlighted. Fundamentals of network planning, implementation, and troubleshooting finish the session.

Mammography Quality Standards Act (MQSA)

The Mammography Quality Standards Act of 1992 requires that all facilities producing, processing, or interpreting mammograms have been certified by the Secretary of the Department of Health and Human Services by October 1, 1994. Failure to comply could result in civil penalties of \$10,000 per day. This seminar discusses the requirements for certification.

Image Systems Evaluation (Hands-On Demo)

The fluoro-imaging chain has many variables and components that must complement each other to ensure an acceptable image. This session will present and demonstrate the techniques used by imaging experts to evaluate and optimize fluoro images. Subjects will include image optimization, resolution, image specifications, test equipment use, and common imaging problems. It will be held at the DITEC Training Center.

Strategic Planning in the New Century

The need for strategic planning in today's business environment cannot be overemphasized. As business systems become bigger and more complex, proper planning is essential for organizational survival. This seminar will cover the fundamentals of planning, as well as advanced, new techniques that can be utilized to ensure success and growth in future endeavors.

Asset Management—Data Tracking Reporting

A very important function of asset management is the data tracking and reporting piece. This session will discuss JCAHO requirements, what hospitals must do and how they must do it, as well as provide a live demonstration of an actual database. Emphasis will be on the information reports generated for hospital management.

Principles of Diagnostic Ultrasound

Due to its relatively compact design, advanced digital circuitry, and ease of maintenance, ultrasound is proving to be another source of revenue for ISOs and a cost-savings factor for in-house programs. This session is designed to introduce the skills necessary to service ultrasound with an emphasis on image analysis and operation.

Picture Archiving and Communications Systems (PACS)—Hands-On Demonstration

Advancements in electronics, communications, and computer hardware and software, as well as the high cost of film, have caused hospitals to consider filmless radiography. Picture archiving and communication systems are now available from several manufacturers. This session will introduce the fundamentals of PACS and will include a hands-on demonstration of the concepts using a PACS workstation simulation.

Mammography Physicist Testing (Hands-On Demonstration)

The current trend of regulation and accreditation in mammography requires all those who are associated with this modality to upgrade their skills and knowledge. This session will cover the physicist tests mandated by the Mammography Quality Standards Act (MQSA) to ensure the lowest dose to the patient as well as the highest-quality image. It will be conducted at the DITEC Training Center.

Industry Future—Panel Discussion

Today's environment of "health care reform," managed care, consolidation, and multi-vendor service presents challenges and opportunities never before encountered in our profession. Guest panelists from organizations that have taken on the challenges of leading the industry will guide the discussion as we head into the new century.

Pitfalls of Purchasing Refurbished Equipment

Refurbished equipment provides for considerable savings over new equipment in many cases. Some organizations claim to provide "refurbished" equipment when, in reality, the equipment is only repainted. This session will discuss how to avoid trouble when purchasing refurbished equipment by getting it in writing, getting references, visiting facilities, and determining whether it "feels right."

Principles of MRI

Magnetic resonance imaging has been used in a clinical setting for years. This technology is another opportunity for in-house groups and ISOs to expand into servicing. This session will cover the MRI principles of resonance, gradients, RF, image analysis, and algorithms, as well as an overview of the hardware needed to produce an image.

Imaging Glassware—Generation to Display

This comprehensive session will describe the fluoroscopic X-ray system from the inception of the X-ray beam to the television monitor output. This detailed description includes the X-ray tube, both glass and metal technology, image intensifier/amplifier, camera, tube or solid state, and the monitor. Monitor discussions will include everything from normal 525-line systems to 5-megapixel PACS units.

Principles of Diagnostic X-Ray Imaging

This session is intended for managers, sales professionals, and service professionals who need an introduction or refresher course in the technical aspects of radiology and fluoroscopy. Topics will include diagnostic imaging system components and factors that affect image quality.

Pulsed Fluoroscopy

The pulsed fluoroscopy technique offers advantages over conventional continuous fluoroscopy and is becoming a popular option. This session will cover the advantages of pulsed fluoro as well as the equipment changes needed to control the exposure in X-ray systems.

Digital Diagnostic Imaging

Advancements in electronics as well as their reduced price have permitted an increase in the use of computers to perform digital imaging. This session will cover the most widely used methods of producing digital images, including mask subtraction, road mapping, temporal averaging, ejection fraction, wall motion, and many other imaging algorithms.

Imaging Technology for the New Century

Medical imaging has come a long way since Roentgen's first X-ray in 1895. Armed with such techniques as MRI, CT, and ultrasound, physicians now peer inside the human body in ways that were previously done only through surgery. But even that technology is changing. DT-MRI, OCT, VCSLs, T-Scan, and a host of other techniques loom on the horizon. This seminar brings you to the leading edge of these exciting technologies.

Adding Style to Your Reports

The Microsoft Office Suite provides a lot of capability to produce good-looking and effective reports. Armed with some basic tips and tricks, you can create easy-to-read custom reports for the equipment you service.

ISO 9001:2000 VS ISO 9001:1994

ISO 9000 is sweeping the world, rapidly becoming the most important quality standard. Thousands of companies in over 100 countries have adopted it, with many more in the process of doing so. Why? Because it controls quality, it saves money, customers expect it, and competitors use it. If you are currently ISO9002/3:1994 certified, you will now need to become ISO9001:2000 certified. This seminar explains how to make the transition.

Principles of Nuclear Medicine

This session will provide introductory knowledge in the principles of servicing nuclear medicine systems. Topics will include nuclear physics, gamma detectors, pulse-height analyzers, x-y-z coordinates, flood correction, and image formation, as well as an overview of the hardware needed to produce an image.

High-Frequency Principles & Troubleshooting

During the 1980s, high-frequency KV circuits became technically feasible as the switching times of high-power SCRs got faster. The concepts of high-frequency KV and mA control have become the state of the art in today's X-ray systems. This session will cover the concepts and troubleshooting techniques needed to maintain these systems.

Non-Invasive Measurements: Past, Present, & Future

This session will discuss some of the advances in non-invasive X-ray measuring equipment. Included in this explanation are techniques associated with standard as well as specialized measurements (e.g., cine, non-invasive mA, fluoro, portables, etc.) In addition, a new method and device for focal-spot measurements will be presented.

Resource Services Program

DITEC offers the DITEC Resource Services Program (DRSP), which is aimed at servicers of diagnostic imaging technologies. Below is a listing of services provided through that program.

- Telephonic support assistance
 - Management
 - Technical
- Management information reports of DRSP usage
- Specially discounted on-site technical assistance
 - Provided by DITEC or other appropriately trained individuals
- Specially discounted management assistance
 - Provided through our network of management consultants
- Special 10% tuition discount on "closed door" on-site training by DITEC
 - For organizational and corporate members only
- 50% discounted attendance at yearly DITEC Conference
 - Technical and support services exhibits from national suppliers
 - Over 60 special seminars presented by industry leaders
 - Special panel discussions on the industry, in-house, and independent service
- One Call Parts Sourcing Assistance saves money, time, and aggravation:
 - Help to troubleshoot and identify the fault

- Help with the part identification
- Have an inventory of surplus systems and parts
- Research suppliers of the best price and quality
- Get the item for you or send you directly to the supplier
- DITEC Parts Sourcing Directory on the World Wide Web—a listing of suppliers and contacts for:
 - Equipment
 - Parts
 - Glassware
 - Other services

- DITEC INK Quarterly Newsletter
 - DITEC news
 - Industry news
 - Featured organization—featured articles—technical tips
 - FDA compliance updates
 - Special test equipment loans

Clinical Engineering and Nursing

Thomas J. Bauld, III

Biomedical Engineering Manager, Riverside Health System, ARAMARK/Clinical Technology Services
Newport News, VA

Joseph F. Dyro

President, Biomedical Resource Group
Setauket, NY

Stephen L. Grimes

Senior Consultant and Analyst, GENTECH
Saratoga Springs, NY

Impact of Technology on Clinical Engineering and Nursing

Advanced technology has been a mixed blessing. Its positive impact on health care has been the prolongation of life and the improvement of the quality of life. It also has created immense problems, particularly by influencing illness patterns to shift from the acute to the chronic, engendering a complex medical instrumentation environment where stress, bewilderment, intimidation, and fear can abound. The expansion of technology has increased the complexity of nursing practice and has raised ethical and legal questions never before confronted (Stephens, 1992).

The resolution of most of these issues requires an interdisciplinary approach; many of these issues are of direct concern to clinical engineering and nursing, and they face the rest of the health care team as well.

Some of the consequences of advancing technology include the following:

- The failure to utilize a technological advance can increase liability exposure.
- An assessment must be performed to determine when it is appropriate to use an innovative technology.
- Technology's advances will enable more home care of the chronically ill, raising the issues of ultimate responsibility for the safety of home-use devices such as ventilators, infusion pumps, dialysis machines, and apnea monitors.
- Advancing technology may increase or decrease the incidence of medical malpractice litigation. Technology that requires excessive nursing attention fosters an impersonal climate because less time is available to spend interacting with the patient. Technology that is less nurse-dependent promotes a more personal experience, and a patient's favorable impression of his hospital stay often mitigates the legal consequences of complications.

Changing legal attitudes in response to technological advances have resulted in additional responsibilities for nurses. Recognition of the day-to-day condition of devices, the need for in-service training, and signs of incipient device failures are essential components of a sound medical device safety program required by legal and regulatory authorities. Diligence in reporting device-related incidents and accidents ultimately results in the reduction of liability exposure. Full cooperation is recommended in incident investigations. The systems approach to incident investigation identifies the contribution to the incident of the device manufacturer, the maintainer, the facility environment, the patient, the family members, or the clinical users.

Today, microprocessor-based monitors provide more information and improved accuracy. Unless this information is assimilated and appropriate action taken, nurses could be liable for rejecting it. Advancing technology places significantly more responsibility upon the nurse. Efforts to reduce liability exposure must begin with education. Education can help to minimize the likelihood of improper use of state-of-the-art medical devices (Dyro, 1983a).

Nursing Education in Technology

The lack of medical instrumentation courses in nursing curricula is often cited as an explanation for difficulties that a nurse might experience in the use of a medical device (Harton, 1982; Schultz, 1980; Shaffer, 1983; Laing, 1982). However, some educators question whether heavy emphasis on the latest technological advances is appropriate in the nurse curricula. These educators call for a softening of the technical-mechanistic approach to care, particularly in the critical care setting (Zemaites, 1982).

Nursing education in this country began with the Nightingale schools, which stressed a highly disciplined, apprenticeship approach to the education of the "trained nurse" (Notter and Spalding, 1976). Early in this century, it was recognized that the hospital-based diploma program's educational function was compromised by the hospital's manpower needs. As nurses sought autonomy, the locus of educational preparation shifted from the hospital-controlled-diploma nursing program to the collegiate-degree-granting institutions. Three educational routes exist, i.e., associate's degree, diploma, and baccalaureate in nursing, for entering nursing practice and for attaining eligibility status for registered nurse licensure examination.

In 1965, the American Nurses' Association (ANA) declared that education for those who work in nursing should take place in institutions of higher education. Professional nursing-practice education should consist of a minimum of a baccalaureate degree in nursing, and technical nursing practice education should consist of a minimum of an associate's degree in nursing (ANA, 1965). The ANA contends that diploma and associate's degree nurses should be recognized as "technical nurses" and baccalaureate degree nurses should be recognized as "professional nurses."

Technical nursing practice is the direct nursing care in areas of physical comfort and safety of patients who have health problems. The technical nurse performs nursing functions with patients who are under the supervision of a physician and/or professional nurse and assists in planning the day-to-day care of a patient and supervising other workers in the technical aspects of care. Technical nursing practice involves coordination of functions with other health services and the provision of quality nursing care under the leadership of the professional nurse.

In contrast, the professional nurse is prepared to meet the health care needs of individuals, families, and groups in any setting. The focus for health care involves emphasizing the promotion of health and prevention of illness, as well as caring for clients who are already manifesting health problems. Despite the ANA position, graduates of baccalaureate and associate's degree and diploma programs are still licensed, hired, and expected to function as professional nurses. Graduates of the three different programs must be clearly identified because their education has prepared them for different roles and levels of responsibility (Lunn, 1982).

Integral to the development of clinical proficiency in critical care nursing is the nurse's acceptance and use of technology. However, Harrington (1983) polled 19 medical, nursing, and medical technologist schools and found none that offered courses in medical device technology. A recent study of the way operating room nurses learned to use electro-surgical units showed that most received the required knowledge via instruction from a staff member (94.3%) followed by on-the-job training (85.2%) and orientation (56.6%). On the other hand, only 15.7% received instruction in nursing school (McConnell and Hilbig, 2000).

There is always intense competition for new curricula items, and the clinical topics typically outrank the medical device ones. Because few, if any, basic nursing education programs include either theory or clinical practice related to medical devices, particularly those used in critical care nursing, the burden of preparing clinicians rests with the hospital in-service training department (McConnell and Hilbig, 2000). This is accomplished through specific education strategies that include the clinical preceptor, methods for expanding the knowledge base, self-evaluation, computer-based training, and resource personnel.

The clinical preceptor is selected from a corps of seasoned clinicians who are clinically competent, caring, willing, and able to share their expertise with an orientee. Success depends on the clear identification of preceptorial functions, the support from nursing administration and middle management, the assumption by the preceptor of the teacher/counselor role, and a system to reward and recognize the preceptors for their willingness to share.

In expanding the knowledge base, it is necessary to teach the basics, such as the jargon of bioinstrumentation. Orientees require the basics, while seasoned clinicians, because they are problem-centered, are interested in troubleshooting techniques. Multimedia self-learning modules are a useful adjunct to didactic lectures. Such modules must contain objectives, a pretest, a slide, tape, or filmstrip, and a posttest. Ongoing self-evaluation relies on the identification of essential competencies. Essential members of the resource base include the clinical engineer (CE) and the instrumentation technician, who are members of the critical care team.

The clinical engineer can play an important part in nurse education in medical instrumentation. In the presentation of orientation lectures on medical device safety matters, the clinical engineer can stress the need for the new employee's participation in patient-equipment management and, at the same time, can enhance the identity of the clinical engineering profession (Shaffer, 1983).

Developing Understanding Between Clinical Engineering and Nursing

In the discussion of roles of the CE and nurse, the wide variation in position descriptions and job classifications must be recognized. In both disciplines, a wide spectrum exists. For many, the term "clinical engineer" or "biomedical engineer" means the physical plant mechanic or carpenter who carries a leakage current meter and a roll of inspection tags. Others view the clinical engineer as the designer of artificial hearts. To a large extent, the responsibility and position within the hospital hierarchy depends on the engineer's educational preparation, motivation, and interpersonal skills.

Erroneous Perceptions

The nurse and the CE usually have a clear and accurate perception of themselves (Dyro, 1983b). They have a good sense of themselves, their work, and their relationship to other health care professionals. However, others usually do not perceive these professionals as they view themselves.

The characters illustrated in these two figures are composite sketches of a nurse and a clinical engineer. The caricatures depicted are not those of any particular individuals these authors have encountered. However, they do portray one character's mind's eye view of the other when communication between the two professionals is lacking and when perceptions become distorted. A composite sketch is a drawing based upon the observations of a number of individuals who have a certain perception of a person. The artist gleans certain details from people who have encountered the subject being portrayed—details such as a sloping forehead or bushy eyebrows. There are several limiting factors in the generation of a composite sketch that prevent it from being a perfect representation of reality. Some observers have photographic memories, but many do not. Ability to recall varies from one individual to the next. The length of time over which the observer has encountered the subject and the quality of the encounter affect the resultant perception of the subject. Observers vary in their abilities to listen and to understand what they are told. If one never has an occasion to see or to talk to the subject, one may form images based upon ways that person has altered the environment. For example, one knows that there is a Sasquatch, Yeti, or Abominable Snowman because one can see the big footprints in the snow.

The two figures illustrate perceptions of individuals when an observer has little or no contact time with the person being described. The illustrator interviewed several CEs and biomedical engineering technicians (BMETs) whose exposures to nurses were brief and who based their descriptions on the results of their perceived nursing interactions with medical devices. The BMET, who had been called upon to repair a monitor that had been smashed to pieces, imagined that the nurse had great strength and possessed a stout frame and muscular arms and legs. The BMET imagined that the nurse transported physiological monitors by dragging them across the floor by the line

cord because several monitors under repair had damaged strain reliefs and broken insulation at the plug-to-cord junction. A CE felt that a nurse was always equipped with a gasket scraper for fine-calibration adjustments and a generous supply of white tape (which is used to fix a vast array of medical devices) because the CE frequently observed white tape liberally applied to loose connectors and broken parts. Other imagined features included a decorative necklace of paperclips, which were used to hold things together, and hair containing an ample supply of bobby pins, which had been found jammed into switches holding down alarm-reset buttons so that nuisance alarms would not sound. Improper settings on devices led the CE to believe that the nurse had extremely poor eyesight and that she must wear very thick glasses. The CEs and BMETs interviewed assumed that nurses have great difficulty with their vision because on a number of occasions they responded to calls from nurses who reported not being able to find an ECG cable, only to find that the cable lay on the patient's bedside stand. On the basis of these observations from the CEs and the BMETs, the illustrator composed the Gorilla Nurse.

Several nurses were asked to describe the clinical engineer. They responded with a description of a troglodyte or a caveman-like person who lives somewhere deep in the bowels of the building and belongs to the biomed tribe, which includes carpenters, biomedical engineers, biomedical engineering technicians, biomedical equipment technicians, repair men, maintenance, and clinical engineers. Accordingly, the artist rendered the sketch of the Caveman Clinical Engineer. He gave the Neanderthal CE a sloping forehead. The CE's brain case is of diminished proportions because in his capacity he would not possess the higher-level intelligence required to understand the principles of hemodynamic monitoring or electrocardiograph measurement. The CE has with him several essential items, such as inspection stickers. These are all prenumbered and preapproved. The nurses observed these tags being hurriedly placed on equipment just prior to Joint Commission on Accreditation of Health care Organizations (JCAHO) inspections. The CE carries an electrical leakage current tester because, as far as the nurse is concerned, the only inspection that the CE performs is a check of the stray electrons lurking behind control knobs, ready to spring upon the unwary. He has an ample supply of tools for fixing the laundry chute, the car, the hi-fi, and the radio.

The sketches depict the nurse and CE as they are sometimes seen by each other. Effective communication between members of the two professions is a good first step toward correcting some misconceptions.

Accurate Perceptions

In 1982, the Association for the Advancement of Medical Instrumentation (AAMI) 16th Annual Meeting featured a technical session on a systems approach to medical device safety, i.e., the identification of the five elements affecting medical device malfunction: the user (often the nurse), the device (and the maintainer, often the clinical engineer), the facility, the environment, and the patient. During that session, a clinical nurse specialist, in addition to showing ways that nursing influenced patient safety, stressed the need for close cooperation between the two disciplines of nursing and biomedical engineering (AAMI, 1982). Her colorful images of the nurse "air-head" and the clinical engineer "Maytag repairman" were attempts to illustrate that members of both disciplines are often stereotyped by each other and by those outside of their respective fields (Dyro, 1983c). She showed that the images were not accurate, that the critical care nurse is technologically sophisticated, that the nurse often contributes to the advancement of medical device technology, that clinical engineers complement nurses on the critical care team, and that benefits could be derived from interaction between the two disciplines. One of the first clinical engineers the world knew was the nurse Florence Nightingale, whose establishment of hospitals to treat the sick and wounded during the Crimean War demonstrated that engineering the environment to improve sanitation and infection control reduced morbidity and mortality.

Clinical Engineer as Educator

There are few endeavors where clinical engineers can have a greater beneficial effect on health care than in their role as educators. Knowledgeable individuals are naturally limited by time and location in what they can accomplish with their knowledge. Teachers dramatically extend their influence by sharing their knowledge with others. With their understanding of technology and its application in the clinical environment, clinical engineers are in a unique position to judge the technology-related information to share, and with whom to share it, in order to make the most profound impact on the quality and efficacy of health care.

A clinical engineer's most important teaching role is in the instruction of clinicians on the proper use of medical devices. While some staff might have extensive training in the operation of specific medical devices and systems (e.g., medical imaging technicians, laboratory technicians, and respiratory therapists), most physicians and nurses operate medical devices incidentally to their primary roles. As a consequence, their expertise regarding the effective use of medical devices is often uneven. Coordinating their efforts with the organization's educational team, CEs should assess the need for staff training and should focus on the development of programs that will be most effective in meeting the organization's needs. Service histories can be an effective tool for identifying areas in which training would be beneficial. A significant number of service reports on a particular model or type of device where there was "no problem found" or "use related" problems a strong indication of the need for staff training. Other means of identifying areas where medical device training is needed include staff surveys, incident reports, and anecdotal reports.

Generally, staff training on medical devices by CEs should include proper set-up procedures, setting alarm parameters, indications and contraindications for use of the device, problems to expect during routine use, and basic troubleshooting techniques. A review of clinical application procedures by the nursing educators should cover step-by-step use of the device's various operating modes. There should be a general discussion of the indications and contraindications for use of a device and the device's effect when used in these circumstances. Finally, staff training should address relevant troubleshooting techniques that will help to ensure that the patient benefits from the best application of the device while reducing the likelihood of unnecessary clinical down time and service calls.

Clinical Engineer in Nursing Support

Clinical engineering typically supports nursing in a number of ways, several of which are listed below:

- Introduction to the use of new systems, and refresher training on existing systems
 - Indications and contraindications
 - Proper use
 - Basic troubleshooting
- Provide “help desk” services; i.e., answer technical questions regarding operation of medical devices, including use and basic troubleshooting
- Education based on analysis of “user-related” problems
- Consultation on “technology-related” issues

Customer Satisfaction

In assessing nurse satisfaction with CE support, the CE should ask the nurse the following questions:

- Do you feel that you have been adequately trained in the appropriate use of the medical technology you employ?
- Do you know whom to call with biomedical device repairs or technical issues?
- Are you generally satisfied with the quality of technical advice you receive?
- Are you confident that the medical devices you use are adequately maintained and operating properly?
- Do you know the steps to take in case an incident involving a medical device occurs?

Taking annual user-satisfaction surveys, using the same questions from year to year to track improvements, is recommended. Questions can be changed if there are new areas to explore or if prior results were ambiguous. The most recent version of the survey used at the Riverside Health System in Virginia is shown below.

On a 1 to 5 scale, please rate the performance of the Biomedical Engineering department
Scale:
5 = Very Satisfied 4 = Satisfied 3 = Fairly Satisfied 2 = Poor 1 = Very Poor N/A

Questions:

1. Ease of contacting biomedical engineering
2. Prompt response to service requests
3. Timely completion of equipment maintenance
4. Effective communication on the status of equipment requiring service
5. Technical competence of biomedical engineering personnel
6. In-service training provided on equipment user maintenance requirements
7. Support received from your technology manager, Tom Bauld
8. Assistance with the selection of new or replacement equipment items
9. Professionalism of the staff
10. The overall effectiveness of the biomedical engineering program in meeting your needs

Following the survey process, the results are tabulated. Any questions with a score of 3 or less should be addressed with an action plan, and pertinent users contacted for follow-up.

Teamwork for Risk Reduction

Together, the CE and the nurse form a powerful team that is able to identify and eliminate potential medical device problems that could lead to patient injury. The CE is reasonably certain that when a medical device is evaluated, purchased, inspected, and introduced into use with adequate education of the user, the medical device will perform safely and adequately for its intended purpose. Nevertheless, random component failure may occur, or a weakness in design and manufacture may have gone undetected in the course of incoming acceptance testing. In addition, the clinical environment can be a rather hostile one for a device, and such an environment can be deleterious to proper operation. Device–device interaction, mechanical shock and vibration, fluid incursion, inadvertent and excessive strain, and intentional or unintentional improper use can occur. The nurse is on the front-line of device use. With appropriate knowledge, training, and experience, the nurse can detect adverse device operation before patients are injured. The nurse as problem-spotter is crucial in identifying incipient device failure and bringing this to the attention of the medical device expert, the clinical engineer. Nurses typically are well trained, observant, communicative, persistent, and determined when patient care and safety are at issue.

The Role of Nursing and CE in Technology Management

The CE's role as technology manager depends upon close cooperation of all members of the health care team, not the least of whom is the nurse. Pre-purchase device evaluation, service, utilization, incident and accident investigation, training, and eventual obsolescence are points in the life cycle of a medical device where the nursing input to clinical engineering is needed. For example, utilization of a device might reveal a human factors design flaw that might have escaped detection during incoming inspection because not all clinical conditions or device–device interactions can be predicted and simulated during pre-purchase evaluation and acceptance testing. The nurse is ideally positioned to observe such flaws that could lead to what is often described as user error. User error often results from improper ergonomic device design or lack or inadequacy of warnings and instructions. Alerting the clinical engineer to such observations can lead to equipment being designed or modified to minimize the potential for user error.

Training and education is one of the many hidden elements of the life cycle cost of medical technology (Sweeney, 1992). This cost must be factored into any new technology acquisition decision.

Incident Reporting and Investigations

Should an incident occur that can or did adversely affect a patient or anyone else, such as a nurse, doctor, or patient visitor, the prompt reporting of this incident to risk management and clinical engineering can minimize the risk of further device problems and can aid in the investigation of problems that did occur. The CE must train the nurse to follow the correct procedures when an accident occurs and a medical device is involved in the diagnosis or treatment of the patient. For example, the nurse should observe device settings; placement of the device with respect to the patient and other devices; and unusual sounds, smells, or sights, and should list the accessories used; environmental conditions (e.g., temperature, humidity, and electrical power fluctuations); other personnel in attendance at the time of the incident; and the condition of the device immediately prior to the event. The nurse must be trained to preserve evidence (e.g., disposables, leads, connectors, packaging, and package inserts). Complete and accurate documentation of the facts surrounding the incident, recorded as close as reasonably possible to the time of occurrence (attention to the injured party may delay such immediate documentation) will be more accurate than a recollection of events made a day, a week, or a month from the time of occurrence.

Collaboration on JCAHO Activities

The changing requirements for JCAHO accreditation are among the immutable constants in health care. The Environment of Care Standards have patient and staff safety as their foundation. Collaboration among many disciplines is required to meet the standards, with a matrix-management approach becoming more important. Regardless of other disciplines, the two that interact most in ensuring patient safety are nursing and clinical engineering. Working on JCAHO committees, doing environmental and safety rounds, and working together on specific equipment management tasks (such as the scheduled inspection process) all benefit from the close working relationship of staff from each department.

JCAHO Six Patient Safety Goals for 2003

To improve practice in several main areas, the JCAHO has required each institution to develop responses to initially six, and now seven, National Patient Safety Goals. The goals were prompted by Sentinel Events and the realization that the circumstances leading to the Sentinel Events probably existed widely throughout the health care system. Implementation of plans to address the majority of the goals are the responsibility of the clinical staff, but two of them require input and activity by clinical engineering. Unveiled in July 2002, hospitals had until July 1, 2003 to complete the implantation of their plans.

- | | |
|----------|---|
| Goal # 1 | Improve the Accuracy of Patient Identification
JCAHO Recommendations |
| A | Use at least two patient identifiers whenever taking blood samples or administering medications or blood products. |
| B | Prior to the start of any surgical or invasive procedure, conduct a final verification process, such as a “time-out,” to confirm the correct patient, procedure, and site, using active, not passive, communication techniques. |
| Goal # 2 | Improve the Effectiveness of Communication among Caregivers
JCAHO Recommendations |
| A | Implement a process for taking oral or telephone orders that require a verification. “Read-back” of the complete order by the person receiving the order. |
| B | Standardize the abbreviations, acronyms, and symbols used throughout the organization, including a list of abbreviations, acronyms, and symbols <i>not to use</i> . |
| Goal # 3 | Improve the Safety of using High-Alert Medications
JCAHO Recommendations |
| A | Remove concentrated electrolytes (including, but not limited to, potassium chloride, potassium phosphate, and sodium chloride >0.9%) from patient care units. |
| B | Standardize and limit the number of drug concentrations available in the organization. |
| Goal # 4 | Eliminate Wrong-Site, Wrong-Patient, and Wrong-Procedure Surgery
JCAHO Recommendations |
| A | Create and use a preoperative verification process, such as a checklist, to confirm that appropriate documents (e.g., medical records and imaging studies) are available. |
| B | Implement a process to mark the surgical site and to involve the patient in the marking process. |
| Goal # 5 | Improve the Safety of using Infusion Pumps
JCAHO Recommendation |
| A | Ensure free-flow protection on all general-use and patient-controlled analgesia (PCA) intravenous infusion pumps used in the organization. |
| Goal # 6 | Improve the Effectiveness of Clinical Alarm Systems
JCAHO Recommendations |
| A | Implement regular preventive maintenance and testing of alarm systems. |
| B | Assure that alarms are activated with appropriate settings and are sufficiently audible with respect to distances and competing noise within the unit. |
| Goal # 7 | Reduce the Risk of Health care–Acquired Infections
JCAHO Recommendations |
| A | Comply with current CDC hand-hygiene guidelines. |
| B | Manage as Sentinel Events all identified cases of unanticipated death or major permanent loss of function associated with a health care–acquired infection. |

For clinical engineers, most attention has been directed to National Patient Safety Goals #5 and #6 because they work with instrumentation that is routinely part of the institution's equipment management plan and clearly are within the nursing/clinical engineering collaboration arena. The issue of effectiveness of clinical alarms is an area that has needed attention for a long time, and one sees a wide variety of approaches being developed nationwide that will lead to improvements in patient care because of the collaboration of nurses and clinical engineering professionals.

Clinical Alarm Audits: A Research Opportunity

One way to evaluate the effectiveness of clinical alarms is to perform an audit of what occurs on a nursing unit when device alarms are activated. At the Riverside Regional Medical Center, the alarm audit has evolved into a long-term, quality improvement research project involving the School of Professional Nursing and the Clinical Engineering department. A multidisciplinary team initially proposed an audit process and developed an audit tool, which were piloted with nursing managers and staff-development educators. After consideration of the results, a lack of consistency, difficulty in tabulating data, and difficulty assigning staff resources to the task were found. Discussions with the director of the School of Professional Nursing revealed that one of the senior courses had a requirement for the students to perform an audit. The instructors were enthusiastic, as were the nurse managers. The audit tool was refined to provide data in a more measurable format so that trends of the audit outcomes could be developed. As an added benefit, the opportunity for the Clinical Engineering department to collaborate with senior nursing students provided an excellent environment in which to develop working relationships and understanding of each discipline's abilities.

Education Opportunities and Techniques

Rationale for Educational Programs in Medical Device Technologies

Experts in equipment-related injuries believe that the vast majority of incidents are due to user error, not equipment malfunction. As the complexity and sophistication of equipment grow, regular training of equipment users becomes ever more important as an element of technology management and an integral part of technology-related quality assurance and risk management. The scope of equipment training should include not only hospital personnel but also physicians and any others who regularly use equipment, e.g., residents, medical students, and allied health students.

In particular, the nurse, as operator of many sophisticated and complex medical devices, needs in-service education and training to keep pace with the rapid advances in health care technology. A strong education program is an indispensable means of maximizing the use of medical device technology within a hospital (Dyro, 1988).

What the Nurse Must Know

CEs have a unique perspective not only on the benefit of technology, but also on its risks. The use of technology in the health care environment where there is a constant staff turnover and procession of patients, many made more vulnerable because of their situation, introduces significant risks. There are risks in the ways in which each new medical device interacts with other devices and systems, with a complex environment containing a diverse range of electric, electromagnetic, radiological, thermal, chemical gas/fluid, biological, auditory, and material factors, and with people.

CEs can assist in the developing educational programs that acquaint nurses with relevant risks and can provide them with the knowledge and tools that they need in order to manage and minimize those risks. Such training should emphasize the importance of preempting problems by reporting anything out of the ordinary with a medical device (e.g., signs of physical damage, inadequate cleaning, missing components, loose controls, or unusual odors or sounds), a description of situations in which use of a device should be terminated (e.g., when alternate devices are available, when the potential risk of continuing use outweighs the benefit of continuing), and the procedure for reporting (e.g., to report service needs to clinical engineering). Training also should include appropriate precautionary steps when using a device. This typically includes a brief pre-operational physical inspection and operational check, thus ensuring a safe environment (e.g., safe electrical and gas supply systems and operating away from combustibles or devices that could interfere with proper operation).

Nurses must be trained as to what to do when a device failure or incident occurs. This should include noting circumstances of use, device settings, other devices, and accessories used. Their training should include the procedure for reporting this information, as it is critical in determining remedial actions that are necessary to prevent any recurrences.

Equipment users must be trained before new equipment is introduced into patient care, and they also should receive annual training in equipment use. However, the annual in-service training should *not* simply cover fundamentals of equipment use, because most of those receiving the refresher training use the equipment regularly and can be presumed to know the basics. Rather, the annual refresher should concentrate on life-support or problem-prone types of equipment, particularly problems that actually have occurred over the past year, ways in which they can be prevented, and ways in which the users can troubleshoot and resolve them.

Education material for training of nurses in medical instrumentation is available from a number of sources (Webster, 1998; Carr and Brown, 1998; Aston, 1990). The nursing literature contains some articles on medical instrumentation (Miller and Zbilut, 1983). Medical device manufacturers are also abundant sources of technical information, especially as it relates to the products that they manufacture (Sweeney, 1992).

Educational Venues

The clinical engineer is involved in nurse education in the following situations:

- New employee orientation
- Formal in-service continuing education programs
- Equipment fairs
- Informal, as-needed education during medical device problem reports and requests for service
- Training programs presented when new equipment is introduced
- Participation of clinical engineering in patient care areas, such as by clinical instrumentation specialists

Orientation

An orientation lecture by clinical engineering on medical device safety acquaints the new employee with the essentials of medical device safety and the role and function of the clinical engineering department, and ways to request service assistance. At orientation, the informal educational role of CEs is emphasized.

Formal In-Service Programs

CEs should make a multicomponent educational effort to train hospital staff in medical device operation and safety. The staff development department, together with the clinical engineering department, should develop orientation programs that consist of lectures presented by nursing staff educators and self-study modules on subjects such as ECG, cardiac-arrest response, IV therapy, and respiratory care. Training in equipment use is usually best conducted by someone from the same discipline as those being trained, such as a staff development nurse for nursing personnel or a technologist supervisor for radiology or respiratory therapy. However, CEs should participate in the development of the content, especially when problems of equipment use are to be discussed. There is an increasing emphasis on computer-based self-training, especially for a set of mandatory topics done on an annual basis to ensure competency. Clinical engineering input into these computer-based courses is beneficial.

Situational Education and Training

Most training and education is on an individual basis and occurs in answer to a nurse's request for service, a time at which the nurse has the highest level of attention and interest in the problem occurring with the medical device. Analysis of computerized medical equipment management system failure categories such as operator error and equipment abuse can influence the course of educational efforts. Focused training to particular groups or on particular device types can be given if failure analysis indicates that it is warranted.

New Equipment Introduction

During the acquisition and capital review process, the CE must ensure that all educational training tools are acquired along with newly acquired medical devices. A new device must not be placed into use until the users are adequately trained. Working with the nursing staff development and the manufacturer, the CE can aid in ensuring that an adequate education and training program that will enable all users to be properly trained is put into place.

Clinical Instrumentation Specialists

Clinical instrumentation specialists (CISs) not only deliver medical device service at the point of care, with minimal response time, but also foster improved communication between care-giver and clinical engineering support provider. A CIS group within a clinical engineering department initially formed to provide technical assistance to the open-heart surgical suite and other operating rooms expanded its activities into other critical care areas such as the recovery room, intensive care units, and the labor and delivery suites (Lauria et al., 1986). Expansion of the CIS activities improved the clinical staff's perception of the CE department and provided growth and flexibility for CE personnel involved with this program.

Many hospitals, especially those that regularly perform open-heart and neurological surgery, have a small group of technicians who are dedicated to providing technical assistance and service to the operating room (OR). This type of group typically works directly for anesthesiology or surgery and is responsible for the calibration, repair, and maintenance of OR medical instrumentation. Clinical instrumentation specialists work effectively in areas such as the recovery room, intensive care units, and the labor and delivery suites. Their typical day-to-day activities are the following:

- Providing assistance and guidance to users of medical instrumentation
- Interfacing with staff and supervisory personnel in clinical areas to discuss needs for increased user in-servicing, expediency of CE services, quality of CE services, equipment allocation problems, and overall reliability of the instrumentation
- Providing feedback to CE, staff development, and other support groups within the hospital
- Screening out unnecessary requests for equipment repair service so that BMETs are not needlessly overloaded and so that equipment is not taken out of service without good reasons
- Modifying or developing new test procedures for use by BMETs and clinical staff
- Performing pre-purchase evaluations and assisting in clinical studies involving medical instrumentation
- Assisting clinical and CE staff in performing in-house research and development

Expansion of the CIS program resulted in a more positive perception of the role of CE by the clinical staff. Users reported that equipment problems were solved more quickly and

that their understanding of the equipment improved. The program effectively remedied instrumentation problems before the clinical staff lost trust in either the equipment or the CE staff.

Teaching Methods

The training must utilize formal and informal methods, taking into account principles of adult learning and instructional design. All available tools, such as videos, audiotapes, slides, books, manuals, posters, and simulators should be obtained. Pre- and post-tests are vital to the assessment of the real effectiveness of the training.

The following is a set of questions that will assist the clinical engineer and nurse staff development team in determining the extent and nature of training:

- What are the training requirements for this equipment?
- Can the suggested training program be customized?
- Who will deliver the training?
- How many users will need to be trained?
- Will a train-the-trainer method be used?
- Can clinicians be relieved from their duties during training?
- Can cost-effective personnel arrangements be made for off-shift training?
- Is there a financial commitment from management for an effective training program?
- Is there a hospital or nursing policy that mandates training for all new staff and new equipment?
- Do staff changes, technology changes, regulatory requirements, and other factors make an ongoing original equipment manufacturer (OEM) training agreement a financially sound investment?

Information about proper equipment use must be explained in a manner that those receiving the training can understand in order to be effective. Discussions between the clinical engineering representative and the staff development nurse or other experienced trainer, in advance of the training session, can be helpful in identifying the best way to approach the material to be covered. Adult learners absorb the material in a variety of ways, but the most effective method has the learners demonstrating the required tasks under the observation of the instructors. This has significant implications for the quantity of equipment and the number of instructors needed for in-services.

Information must be transmitted not only accurately but also in a way that captures the interest of the audience. The educator must seek out ways in which the presentations captivate, rather than overload, the student (Berens, 1988). Recent developments in simulation technology offer the potential to enhance training to a new level that involves not only operational features, but also assessment and prediction of the patient’s clinical changes resulting from changes in equipment settings.

Audits of many clinical engineering departments have shown that the approach taken by clinical engineering personnel is crucial to the effectiveness of their training (ECRI, 1989). Those who conduct the training must be sensitive to the fact that most equipment users have little or no knowledge of electronics or engineering.

It is vital that technical staff involved in educating clinicians avoid the use of jargon and acronyms. While these forms of communication can facilitate conversations between peers, they will impede understanding when used in an interdisciplinary setting.

Indicators of Education Efficacy

Equipment-related training should be monitored and assessed regularly for its effectiveness, either by the clinical engineering department or by the individual departments conducting it. Training provided by manufacturers should be included in such reviews. Camplin (1988) recommended the following ways in which effectiveness of education can be measured: incident or accident reports, feedback from equipment tests and inspections, findings from hazard surveillance, critiques of drills and exercises, surveys, unit rounds, and inspections. Risk management, quality assurance, and safety management are all means of obtaining and processing data. Other measures include pre- and post-test and follow-up post-tests several months after the training. One objective assessment that can be monitored and trended over time as a performance indicator is the number of use-related work orders for the specific device. During CE rounds, observation of nursing practice in utilizing medical devices can yield evidence of device misapplication, misuse, or abuse.

Evaluation of Effectiveness of In-Service Training

Table 76-1 shows a training impact assessment form that is used to gauge the effectiveness of medical device training. In this form, corrective work requests are tabulated for six months. The period needs to be at least 6 and, in some cases, 12 months following the training.

Table 76-1 Training impact assessment form

Device Type	Pre-training G			Post-training G			Diff		
	# WRs	Repair hours	Materials cost	# WRs	Repair hours	Materials cost	WRs	Repair hours	Materials cost
PCA pump									
Intensive care									
General care									
Labor & delivery									
TOTAL									

Observation During CE Rounds

Some examples of improper device use that a clinical engineer might observe during rounds, indicating that nurse training, including the following, is required:

- Physical damage, missing screws, missing components, missing accessories
- Battery-operated device not plugged into AC outlet between uses
- Devices with “broken” notes taped
- Devices reported as broken when subsequent testing reveals “no problem found”

Examples of what CEs have observed in the course of rounds are shown in Figures 76-1 through 76-5. On occasion, the CE might witness improper use of medical devices.

Organizational Considerations

Administration

Those who are responsible for the administration and management of hospital affairs must ensure that full support is given to the CE department’s role in education and training of clinical personnel with regard to medical device operation, utilization, and safety. Policies and procedures should describe this educational component of the CE department. The relationships with nursing staff development should be described.

Policies and Procedures

Policies and procedures that pertain to the role of clinical engineering in nurse education should include the following elements:

- Staff members must be trained prior to their initial use of medical equipment, and periodically as necessary thereafter. Training should include the following:
 - Indications and contraindications
 - Proper operation
 - Basic troubleshooting
 - Appropriate “backup” procedures when the device fails
- Procedures to follow when incidents and accidents occur involving medical devices

Clinical Engineering Department Roles and Responsibilities

The following are typical roles and responsibilities of the clinical engineering department with regard to nursing and nursing education and training in particular:

- Equipment life cycle cost: nurse (user) training is a component of cost
- Incident investigations
- Accidents: evidence preservation and sequestering techniques

Figure 76-1 White tape, a.k.a. “nurse tape,” used to fasten monitor to stand.

Figure 76-2 White tape used to secure ill-fitting electrical power cord to bed receptacle.

Figure 76-3 Improperly stacked monitor.

- Recall and hazard-report management
- Equipment selection and clinical trials
- New-staff orientation to electrical safety issues and department operations
- User training based on tracking instances of user error by device type and department
- Development of competencies for equipment use
- Risk management
- Obtaining replacement user manuals

Accountability and Appreciation

Equipment control records should include detailed records of the equipment types and the departments where training was provided, as well as documentation of persons who have

Figure 76-4 A 12-lead EKG interface secured with multiple layers of clear tape.

Figure 76-5 Multiple cracks observed in the plug of a nebulizer's power cord.

provided the training. In a similar fashion, nursing and other departments are responsible for maintaining records of persons who were trained on particular equipment. Computerized tracking of employee attendance and program evaluation facilitates JCAHO documentation and reporting requirements (Franklin and Landureth, 1988). Nursing policy indicates that there is a formal process to address training, and documentation demonstrates that the training has been done. However, JCAHO surveyors go beyond merely verifying that personnel files document training. They assess whether or not the clinical staff can demonstrate and use the knowledge acquired.

While the health care environment is serious and professional, the ability to celebrate milestones and recognize co-workers in their profession's special week or month is a golden opportunity to show appreciation and to build relationships. Many clinical engineering departments host an annual food event for colleagues in nursing, radiology, and the laboratory. At Riverside Health System, the CE department held an ice cream social during Laboratory Week and provides multiple flavors and all of the toppings for personnel from all three shifts at all three of our hospitals. For Radiology Week, the department provided pizza lunches. During Virginia's Biomedical Equipment Technician Week, the department hosted open houses with snacks, popcorn, slushies, and a random drawing for a dinner certificate. Each of these events was fun and enjoyable for all involved. Some of the benefits include an opportunity to have the service staff interact with the customers in a nonservice environment, a chance to show appreciation and recognition for the work of the clinical staff, and a way to have departmental or institution-wide announcements that build recognition of clinical engineering as part of the health care team.

Summary

The advancement of medical device technologies has resulted in greater numbers of complicated devices. Nurses, clinical technicians, and physicians have more effective tools for caring for the patient, while at the same time they bear an increased burden of responsibility to use devices properly.

The partnership role of clinical engineers is nowhere more evident and needed than with the largest group of health care workers, the nurses. CEs and nurses are beginning to perceive each other's profession with more clarity and appreciation. The nurse perceives the clinical engineer as a skilled professional who has expertise in the design, utilization, and management of medical devices, and looks to the CE as an ally in ensuring that the proper devices are introduced into the clinical arena and that they are maintained in a safe and reliable condition throughout their life cycles. Nurses seek out and welcome the educational support provided by CEs. CEs, for their part, understand the particularly demanding work that nursing entails, and they strive to support that aspect of the work that entails the utilization of technology in support of patient care. Customer satisfaction surveys are effective in increasing the perception of nursing needs and CE responsiveness to those needs.

By close CE–nurse collaboration in many aspects of the equipment management life cycle, such as pre-purchase evaluation, postmarket surveillance, and training, a significant improvement in medical device utilization and patient safety can be achieved. Capital-equipment acquisition committees, accident/incident investigation teams, and educational programs are among those elements in the technology management process where such close teamwork is particularly beneficial.

The use of performance indicators such as repeat problems, no problem found, and user error can assist the CE in assessing the effectiveness of medical device training. Walking around and observing ways in which technology is utilized yields further insight into equipment use and enables refinement of educational programs and risk-reduction efforts.

Administrators must understand that an investment of clinical engineering time in training users of medical device technologies is a wise use of resources, and they must promote such efforts through policies and procedures and adequate financial and managerial support. By training the users to be competent in the effective use of those technologies and to report any perceived risks, incidents, or close calls associated with the utilization of equipment, clinical engineers can greatly extend their ability to improve the quality and efficacy of health care delivery.

Retraining Programs

James Gilchrist

Touro College School of Health Sciences
Bay Shore, NY

Program Description

Program Summary

The Institute for Biomedical Engineering and Rehabilitation Services (IBMERS) of Touro College, Bay Shore, New York, offers a Master of Arts (MA) in clinical engineering. In particular, the program attempts to create clinical engineering research as a research-oriented service provider discipline on the graduate level. The program capitalizes on manpower by building onto the Institute's presently offered graduate-level certification program in Clinical Engineering and Biomedical Technology. This program is presently retraining individuals released from the aerospace and defense industries.

IBMERS is uniquely positioned to develop clinical engineering as a discipline, inasmuch as it is a technology-driven, highly productive, biomedical engineering "think tank" with a critical mass of 34 interdisciplinary scientists and engineers who have worked together since 1986. The collective experience includes *Fortune* 500 CEOs, physician-engineers, behavioral scientist-engineers, rehabilitation specialists, computer scientists, and physicians. These individuals represent IBMERS' departments of biomedical engineering, neurocybernetics, neuroscience, behavioral sciences, instructional technology and applied bioscience, and medical humanities. All of the faculty work collectively beyond disciplinary boundaries.

The application areas for employment of graduates include hospital engineering functions such as quality assurance, equipment safety standards, and management of the equipment maintenance function, as well as intra-operative equipment monitoring and the support of highly sophisticated functions such as positron emission tomography (PET); industrial environments including equipment design, manufacturing processes in pharmaceutical and equipment manufacturing environments, FDA regulatory affairs, clinical trials, and beta-site testing; government applications including policymaking for technology, and product evaluation; and rehabilitation environments, including the design of orthotics/prosthetics, wheelchairs, and assistive aids for individual patients. Here, individual patients would consult with the clinical engineer to produce for the individual patient a less restrictive environment. The pool of students included a significant number of displaced defense workers who had more than ten years of experience and many graduate degrees among them. There are in excess of 20,000 of these individuals in the New York City area, thus allowing the opportunity for highly selective admissions standards.

The Faculty

The program faculty members are interdisciplinary active researchers and provide a broad knowledge base for the students. They have experience in the following biomedical engineering specialties: Medical imaging, brain blood flow, Alzheimer's disease, genetic engineering, nuclear medicine, neurophysiology, human information processing, neuro-computing, electrophysiology, systems theory, neuropsychology, clinical engineering, communications systems, magnetic and solid-state physics, electrodiagnosis, acoustics, neurocybernetics, neural networks, automata, medical physics, and continuum neurophysics.

Neuropsychology and Sensory Communication

Curriculum and Course Outlines

Students in the program are trained to gain as complete an understanding of engineering applied to biomedicine and health service delivery as possible. They are prepared in anatomy and physiology as applied to systems sciences and engineering; instrumentation design and equipment safety; sensors and transducers; signal processing; materials sciences; regulatory affairs; rehabilitation engineering and human factors psychology applied to biomedicine; imaging sciences; health information management systems; clinical laboratories; biomedical ethics; statistics; and research design.

The program gives students significant exposure to patent law, forensic examination, manufacturing, hospital inventory control, and FDA regulations. Students hone patient-management skills by research and service in human clinical laboratories in the institute's

clinical facilities as well as in the clinical laboratories of affiliated field sites. Furthermore, students demonstrate the ability to work independently in their chosen field of research and index scientific literature. They make an original contribution of significance to the advancement of knowledge in their chosen field of application in the form of a dissertation.

During the first year of graduate study, all students enroll in a graduate statistical and research design sequence as well as in a physiology sequence. There is also a first-year research requirement that starts the student on an active program of research. The student also must enroll in a sequence of courses designed to give exposure to various topics and methods. In addition, the student must demonstrate competence in a major field of study within the institute. Before admission to candidacy for the master's degree at the end of the first year of study, the student must pass a comprehensive examination in the field of concentration and related fields. This examination tests the student's mastery of a broad field of knowledge, not merely the formal coursework.

A variety of advanced research seminars are taught on a regular basis. Upon completing the comprehensive examination, students engage in dissertation research that culminates in an oral defense.

Two opportunities are provided to pass the qualifying examinations at the end of the second and fourth semesters. Those who fail this examination, or for some other reason do not meet the assessment criteria for entrance into dissertation advisement, are not permitted to proceed further. Students may be awarded the advanced certificate in clinical engineering if they have completed the requirements for that program. The comprehensive examination is held upon completion of the first 33 credits.

Two opportunities are provided to pass both the first qualifying examination at the end of the second trimester and the comprehensive examination at the end of the final trimester. Those who fail the first examination are not permitted to proceed further.

Program Schedule

The program can be completed on a part-time or full-time basis. Full-time matriculated students require a sequence of a minimum of 9 credits per semester to maintain their full-time status for each trimester. Full-time students enrolled in an approved internship require a commitment of at least 20 hours per week for two semesters of 15 weeks each. Part-time students may complete their internship experience by completing the same number of hours as those students with full-time status (i.e., a minimum of 600 hours).

Program scheduling is in a year-round, two-year, three-semester format. Classes typically meet once per week for the required amount of time, depending on the class. Most courses are scheduled at night (some on weekends) to accommodate the working professionals in the program. The following is a sample course schedule for the Master of Arts (M.A.) in clinical engineering:

First Trimester:

	Hours
IBMB 200: Introduction to Research Methods and Methodology	3
IBMN 500: Human Physiology for Engineers	4
IBME 705: Research Advisement	1
IBME 500: Biomedical Instrumentation	1
IBME 510: Microcomputer-Based Biomedical Instrumentation	1
IBMI 500: Business/Management Skills in Biomedicine I	2
	14 credits

Second Trimester:

	Hours
IBMB 210: Multivariate Analysis	3
IBMN 510: Physiology for Engineers II	4
IBME 706: Research Advisement	1
IBME 540: Medical Device Safety and Design	3
IBMI 510: Business/Management Skills in Biomedicine II	2
	13 credits

First qualifying examination

Third Trimester:

	Hours
IBME 550: Biomedical Engineering Laboratory	1
IBMH 500: Biomedical Ethics	3
IBME 560: Electrophysiology and Signal Analysis	3
IBME 710: Dissertation Advisement	2
IBME 750: Internship in Clinical Engineering/Technology	0
	9 credits

Fourth Trimester:

IBME 750: Independent Study	1
-----------------------------	---

One of the Following Three Courses:

	Hours
IBME 520: Medical Imaging Systems, or	3
IBME 530: Principles in <i>In Vivo</i> NMR Imaging/Spectroscopy, or	3
IBMC 540: Digital Image Processing	3

One of the Following Courses:

	Hours
IBME 610: Speech Synthesis Recognition and Acoustics, or	3
IMBC 500: Computer Models of Nervous System Function, or	3
IBMC 510: Analysis of Computation/Systems in Biomedicine, or a specialty course in the student's area of research interest, and	3
IBME 751: Internship in Clinical Engineering/Technology	0
IBME 710: Dissertation Advisement	2
	9 credits

Program and Course Requirements

Requirements for Admission

The following are the criteria for admission to the program:

- A baccalaureate degree in any engineering discipline from an ABET-accredited program or
- A baccalaureate degree in any applied science discipline from an accredited college or university or
- A degree from a foreign university deemed to be the equivalent of any engineering discipline as evaluated by a college-approved credentials service, such as the International Education Research Foundation, Inc.
- Submission of transcripts of undergraduate and all prior graduate work.
- Submission of three letters of recommendation, one of which must be from an individual who will address the matter of the applicant's research potential.
- A clearly written statement of professional goals and how one plans to achieve them.
- By appropriate record of achievement as well as one or more interviews, applicants must satisfy the admission committee that their preparation indicates a high potential for successful advanced study and the requisite skills necessary to work intensively with patients in great need.

Objectives

The program prepares broadly trained clinical engineering professionals who will be competent in a variety of settings and applications including hospitals, industrial design, rehabilitation, government, and the pharmaceutical industry.

Program Requirements

Courses are divided into five areas of specialization for a total minimum number of 45 program credits; these areas are progressively developed over the five levels of the program. The following is a breakdown, by area of specialization, of the required courses in the program.

1. Research Methods and Methodology
2. Systems Physiology for Engineers
3. Clinical and Biomedical Engineering
4. Medical Humanities
5. Professionalism

Research Methods and Methodology

The offerings are designed to teach skills that are useful in understanding, critiquing, designing, implementing, and applying research to help solve and understand clinical problems. (Minimum 12 credits.)

- IBMB 200: Introduction to Statistics and Research Design (3 credits)
- IBMB 210: Inferential and Multivariate Analyses (3 credits)
- IBME 705–706: Research Advisement (1 credit each)
- IBME 710–715: Dissertation Advisement (2 credit each)

Systems Physiology for Engineers

The offerings are geared toward providing a solid intellectual grounding in fundamental and applied human physiology from a systems and designers' viewpoint. Courses offered

are from the Department of Neuroscience and currently are part of the IBMERS course offerings. (Minimum 8 credits)

- IBMN 500: Human Physiology for Engineers I (4 credits)
- IBMN 510: Human Physiology for Engineers II (4 credits)

Clinical & Biomedical Engineering (Minimum 24 credits)

The following courses are required (18 credits)

- IBME 500: Biomedical Instrumentation (3 credits)
- IBME 510: Microcomputer-Based Biomedical Instrumentation (1 credits)
- IBME 540: Medical Device Safety and Design (3 credits)
- IBME 550: Biomedical Engineering Laboratory (1 credits)
- IBME 510: Microcomputer-Based Biomedical Instrumentation (1 credits)
- IBMB 200: Introduction to Statistics and Research Design (3 credits)
- IBME 750–752: Internship in Clinical Engineering/Technology (0 credits)
- IBME 560: Electrophysiology and Signal Analysis (3 credits)
- IBME 580: Mechanics of Materials in Biomedicine (3 credits)

The student must take a minimum of 3 credits from any of the following courses:

- IBME 520: Medical Imaging Systems (3 credits)
- IBME 530: Principles of *In Vivo* NMR Imaging/Spectroscopy (3 credits)
- IBMC 540: Digital Image Processing (3 credits)

Students also must take a minimum of 3 credits from any one of the following courses:

- IBME 600: Biomechanics of Movement and Gait (3 credits)
- IBME 610: Speech Synthesis Recognition and Acoustics (3 credits)
- IMBC 500: Computer Models of Nervous System Function (3 credits)
- IBMC 510: Analysis of Computation/Systems in Biomedicine (3 credits)
- Any specialty in the student's area of research interest (3 credits.)

Medical Humanities (Minimum 3 credits)

Students are required to take the following course:
IBMH 500: Biomedical Ethics (3 credits)

Professionalism (Minimum 4 credits)

Students are required to take the following courses:

- IBMI 500: Business/Management Skills in Biomedicine I (2 credits)
- IBMI 510: Business/Management Skills in Biomedicine II (2 credits)

Students may elect to take the following courses:

- IBMI 520: Introduction to Forensic Examination (3 credits)

Comprehensive Written Examination and Oral Presentation of Thesis

A comprehensive examination is given on some of the coursework taken during this program. The examination is required for successful completion of the program. The comprehensive examination includes anatomy and physiology, electric and electronic fundamentals, safety in health care facilities, and medical equipment problem-solving. The examination is scheduled at the end of the student's fourth trimester in the program. Upon successful completion of the coursework, the comprehensive examination, and the successful completion of the thesis, the student is awarded the degree of Master of Arts in Clinical Engineering and Biomedical Technology.

A variety of advanced research seminars are taught on a regular basis. Upon completing the comprehensive examination, students engage in dissertation research that culminates in an oral defense. The defense is on work that the student has published, either alone or with a faculty mentor in the peer-reviewed indexed scientific literature.

Course Descriptions

Department of Biomedical Engineering

IBME 500: Biomedical Instrumentation

Origins and characteristics of bioelectric signals, recording electrodes, amplifiers, chemical pressure and flow transducers, noninvasive monitoring techniques, and telemetry are covered. (3 credits)

IBME 510: Microcomputer-Based Biomedical Instrumentation Laboratory

Provides hands-on laboratory experience with common biomedical transducers and instrumentation used in physiological and clinical evaluation. Laboratory experiments cover electronic circuit design and construction, analog/digital signal acquisition and processing, principles of hardware and software designs for interfacing biomedical sensors

to general-purpose PCs. Co-requisite: IBME 500: Biomedical Instrumentation (or equivalent).

(1 credit)

IBME 520: Medical Imaging Systems

Provides an overview of the physics of medical imaging analysis. Topics covered include X-ray tubes, fluoroscopic screens, and image intensifiers; nuclear medicine; ultrasound; computer tomography; and nuclear magnetic resonance imaging. The imaging quality of each modality is described mathematically, using linear systems theory, Fourier transforms, and convolutions.

(3 credits)

IBME 530: Principles of In Vivo Nuclear Magnetic Resonance Imaging and Spectroscopy

Emphasizes the applications of Fourier-transform nuclear magnetic resonance (FTNMR) imaging and spectroscopy in medicine and biology. Course topics include review of the basic physical concepts of NMR (including Bloch equations); theoretical and experimental aspects of FTNMR; Theory of relaxation and relaxation mechanisms in FTNMR instrumentation for FTNMR imaging techniques (point, line, plane, and volume methods); and *in vivo* NMR spectroscopy (including volume-localization techniques). Prerequisites: Differential and integral calculus; ordinary differential equations.

(3 credits)

IBME 540: Medical Devices, Safety, and Design

Provides an introduction to biomedical engineering in the hospital. The basic theory of operations of a wide range of medical devices (from heating pads to intensive care monitors and ultrasonic diagnostic units), equipment hazards, and evaluation are stressed.

Co-requisite: IBME 550: Biomedical Engineering Laboratory; IBNM 510: Physiology for Engineers.

(3 credits)

IBME 550: Biomedical Engineering Laboratory

Covers biomedical measurements: Instrumentation analysis and calibration, frequency response of biomedical instrument sources, and reduction of noise in biopotential recordings. Laboratory work includes noise reduction in biopotential amplifiers, circuits, and damping techniques in biomedical recorders. Co-requisite: IBME 540: Mechanical Devices, Safety, and Design; IBNM 510: Physiology for Engineers I.

(1 credit)

IBME 560: Electrophysiology and Signal Analysis

The general theory of decomposition, the Fourier transform theorems, examples of singularity functions, line spectra, sampling, line systems, filters, and spectral analysis are covered. The relationship between Laplace transforms and Fourier transforms, Hilbert transforms, and analytical properties of realizable systems are also covered. Applications to EEG, evoked potentials, event-related potentials, electrocardiography, and electromyography are stressed. Prerequisite: IBME 500: Biomedical Instrumentation.

(3 credits)

IBME 580: Mechanics of Materials in Biomedicine

Materials used for implantable devices are studied. Selected topics include shear center, asymmetrical bending, curving beams, Castigliano's Theorem, the theory of strengthening mechanisms with emphasis on dislocation theory, and physical ceramics.

(3 credits)

IBME 600: Biomechanics of Movement and Gait

Covers isokinetics, gait simulation, CAD/CAM, force velocity relationships, and biomechanical analysis techniques. Computerized cinematography, electrogoniometry, electromyography, and McDonnell Douglas B 200 systems are used.

(3 credits)

IBME 610: Speech Synthesis Recognition and Acoustics

Hardware and software aspects of speech synthesis and recognition are handled. Speech synthesis, recognition, system design, linear predictive coding, synthesis and recognition applications, acoustics, and noise reduction are covered.

(3 credits)

IBME 700: Independent Study in Biomedical Engineering

The topic is agreed upon between the engineering program student and an IBMERS faculty member. Approval of the director of IBMERS is required.

(1 credit)

IBME 750–752: Internship in Clinical Engineering

A supervised field experience for the student is provided in either a hospital engineering department, a hospital-based clinical diagnostic or treatment facility, a biomedical industry design or field-engineering application; or a private, technology-intensive, clinical group practice.

(0 credits)

In addition to taking courses in the Biomedical Engineering department, students take courses in the following departments:

- Department of Neurocybernetics
- Department of Neuroscience
- Department of Humanities in Medicine
- Department of Applied Biosciences
- Department of Biobehavioral Science
- Department of Rehabilitation Science

Department of Neurocybernetics

IBMC 500: Computer Models of Nervous System Function

Covers continuum neurophysics, artificial networks, linear and nonlinear models, bifurcation, and chaos theory as vehicles for simulating nervous system function and dysfunction.

(3 credits)

IBMC 510: Analysis of Computations and Systems in Biomedicine

Probability, combinatorics, recurrence relations, and the establishment of asymptotic bounds are studied in relation to biomedical systems.

(3 credits)

IBMC 540: Digital Image Processing

Reviews fundamental concepts of digital-image processing, analysis, and understanding, including modeling, algorithms, hardware components, and system architecture. Theoretical topics include image acquisition (sampling) and mathematical characterization, linear operations on images, image compression, enhancement and restoration, image matching and tracking, and feature extraction. Applied topics: CCD imaging and camera calibration.

(3 credits)

Department of Neuroscience

IBMN 500: Physiology for Engineers I

Defines the functions required of multicellular organisms in order to sustain life in terms of physical, chemical, and system principles. Topics covered prepare the student for more advanced work on a particular organ system. Included are diffusion; osmotic pressure; membrane potential; cellular transport; body fluid compartments; circulation; and the heart as a pump, respiration, blood-gas transport, urine formation, and acid–base balance.

(4 credits)

IBMN 510: Physiology for Engineers I

Defines the functions required of multicellular organisms in order to sustain life in terms of physical, chemical, and system principles. Topics covered prepare the student for more advanced work on a particular organ system. Detailed systems analysis is performed on the nervous system, its organization, self-organizing properties, feed-forward and feedback systems, relax systems, disordered states, communication system principles, and tonic–sensory interactions. Prerequisite: IBMN 510: Physiology for Engineers I.

(4 credits)

Department of Humanities in Medicine

IBMH 500: Biomedical Ethics

Explores ethical issues generated by the application of scientific and technological advances to the preservation, destruction, and programming of human life. Topics covered include ethics in medical research; abortion; euthanasia; behavior control; allocation of medical resources and ethics of the patient physician interaction; and the ethics of technology application.

(3 credits)

Department of Applied Biosciences

IBMI 500: Business/Management Skills in Biomedicine I

Consists of lectures and discussions of topics essential to biomedical technology business development and interaction of practitioners with the biomedical industry. Topics include Concept identification and validation, business aspects of biomedical technology, finance, marketing, product development, good manufacturing practices, regulatory affairs, and distribution networks.

(2 credits)

IBMI 510: Business/Management an Skills in Biomedicine II

Instruction and student participation in interactive setting. Practical application and development in oral and written communication skills required in business and management in the biomedical/hospital industry. Topics include interpersonal

communication, sales, formal and informal presentations of technology, interdepartmental relations, public relations, advertising, correspondence, and business and budget planning.

(2 credits)

IBMI 520: Introduction to Forensic Examination

Survey of the applications of clinical engineering, biobehavioral science, neurosciences, and biomechanics to forensic examination. Topics include the nature and analysis of slip-and-fall injuries, pain management, product design and liability, disability estimation, analysis of residual work function after injury, accident reconstruction, and the process of giving court testimony.

(3 credits)

Department of Biobehavioral Science

IBMB 200: Introduction to Research Methods and Methodology

Three hours of lectures and one two-hour lab per week. Introduces descriptive and inferential statistics and their roles in clinical and technical practice and evaluation. Topics include correlation, regression, t-test, Chi square, ANOVA, nonparametric methods, sample-size estimation, and probability. Also included are topics in experimental design and correlation analysis, including multiple correlation and multiple regression, curvilinear relationships, missing data, interactions, ANOVA and its generalization, logistical regression, selected complex factorial designs, multiple comparisons, and meta-analyses; causal models, construction estimation, and testing of causal models for correlational data. Particular attention is paid to models with unobserved variables.

(3 credits)

IBMB 210: Multivariate Analysis

Scientific concepts, matrix theory, and computer techniques of multivariate analyses for clinical research and evaluation. Topics include cluster and factor analyses, multiple regression, and discriminant functions. Emphasizes research and clinical technology rather than mathematical theory. Prerequisite: IBMB 200.

(3 credits)

Coursework

Program Literature

The majority of literature in the clinical engineering master's degree programs comes in the form of handouts. The handouts are from a variety of sources that include textbooks, scientific journals, product literature, government publications, industry magazines, the Internet, society meetings, and newsletters. While most courses include handouts, the classes that utilize the most handout material include IBME 510: Microcomputer Based Biomedical Instrumentation; IBMH 500: Biomedical Ethics; IBMI 500 and 510: Business/Management Skills in Biomedicine I and II; IBME 540: Medical Devices, Safety and Design; IBMB 200: Introduction to Research Methods and Methodology; IBME 500: Biomedical Instrumentation; IBME 550: Biomedical Engineering Laboratory; IBME 580: Mechanics of Materials in Biomedicine; IBMB 210: Multivariate Analysis; and IBMI 520: Introduction to Forensic Examination.

The following is a sample of some of the textbooks that are required for the clinical engineering master's degree program:

Bronzino JD, editor. *The Biomedical Engineering Handbook*. The *Handbook* is utilized throughout the program as a general reference text or to investigate a specific area of biomedical specialization. Classroom lessons, projects, and homework from the majority of courses listed in this program rely heavily on the *Biomedical Engineering Handbook* for source and reference material.

Curry TS, Dowdey JE, Murry RC. *Christen's Physics of Diagnostic Radiology, 4th Edition*. This textbook is used for a number of courses but mainly for IBME 520: Medical Imaging Systems.

Webster JG, editor. *Medical Instrumentation Application and Design, 2nd Edition*. This textbook is used primarily for IBME 500: Biomedical Instrumentation; IBME 540: Medical Devices, Safety and Design; and IBME 560: Electrophysiological Signal Analysis.

Guyton CA and Hall JE. *Textbook of Medical Physiology, 9th edition*. This textbook is used mainly for IBMN 500: Human Physiology for Engineers I and IBMN 510: Human Physiology for Engineers II.

Tompkins WJ, editor. *Biomedical Digital Signal Processing*. This textbook is used for the course IBMC 540: Digital Image Processing.

Nordin M and Frankel VH. *Basic Biomechanics of the Musculoskeletal System, 2nd edition*. The textbook is used in the course IBME 600: Biomechanics of Movement and Gait.

Computer Hardware and Software

Touro College provides a computer laboratory to all students. Computer software applications are used for the following courses.

IBME 510: Microcomputer Based Biomedical Instrumentation uses the Dataq data-acquisition hardware and software; IBMC 540: Digital Image Processing uses software that comes with the class textbook; IBMB 200: Introduction to Research Methods and Methodology and IBMB 210: Multivariate Analysis both use Systat Statistical Software, and C++ and Visual Basic software are reviewed. All courses require work to be performed with a computer using word-processing programs, spreadsheet programs, and presentation programs, and using the Internet for literature and subject searches.

Class Lessons and Projects

In general, most lecture courses come in the format of lectures, textbook and handout work, class discussions, assigned homework, and class projects. The laboratory courses are hands-on. For the courses IBME 500: Biomedical Instrumentation; IBMI 520: Introduction to Forensic Examination; and IBME 550: Biomedical Engineering Laboratory, the instructor brought in many medical devices for examination and evaluation. Medical devices are operated on simulators. Defibrillators, electrosurgical units, incubators, wheelchairs, pulse oximeters, heart rate and respiration monitors, endoscopes, and orthopedic implants are among those devices utilized in the laboratory setting.

Class projects take the form of hands-on diagnostics and operation of medical devices, oral presentations, and written projects. All projects and written reports are geared toward "real-world" applications, requiring scientific and industrial literature searching, acquiring product literature, and sometimes product samples. In addition, multiple hospital-site visits, society meetings, and guest speakers help to introduce students to the "real world" outside the classroom.

Present Program Status

The following dissertations were written by students who have been awarded the MA in Clinical Engineering:

Robert C. Counts Sr., "A comparative study of an annual quality control report as it relates to computer aided tomography vs. digital fluoroscopy," November 2000.

James A. Gilchrist, "Orthokinetic sensor cuff for the precision measurement of hand flexion; proof of concept study," June 2001.

Masha Lorenz, "The effect of the accessibility of recent data through the Internet on the time an article is accepted for publication in scientific journals," July 2001.

William McConlogue, "Proof of theory, new methods for high speed sorting of solid oral dosage forms by weight," December 2002.

The following programs are currently offered at Touro College:

Clinical Engineering and Biomedical Technology at Touro College School of Health Sciences

Certificate programs

Biomedical equipment technician (undergraduate)

Clinical engineering (postgraduate)

Degree programs

Master of Science in clinical engineering and biomedical technology

Track 1: Clinical Engineering—Degree awarded: Master of Science in clinical engineering and biomedical technology

Track 2: Biotechnology and Bioprocess Engineering—Degree awarded: Master of Science in clinical engineering and biomedical technology (bioprocess engineering track)

78

Techno-Bio-Psycho-Socio-Medical Approach to Health Care

T. G. Krishnamurthy

Chairman, Paramedical Discipline Board, CEP-AICTE, UVCE Campus
Bangalore, India

Clinical Engineering Practices in Developing Nations

It is a universally known fact that two-thirds of the world's population lives in developing and underdeveloped nations. The affluence level in these nations is around 15 percent. About 80% live in semi-urban and rural areas. Socioeconomic, traditional, and cultural parameters effect the preventive, diagnostic, and curative aspects of medical/rehabilitation (medi/rehab) care to a large extent. Developing strategies in a realistic, feasible, need-based, and time-bound plan is necessary. Optimization of the large manpower pool (training and untrained), reasonable material resources, and very limited funds appear inevitable and essential.

The challenge is an integrated interdisciplinary center involving a techno-bio-psycho-socio-medical teamwork approach (Taylor, 1994). Urban, semi-urban, and rural needs differ widely with regard to preventive health aspects. One gets a glimpse of the magnitude of the task only when one actually visits the rural and semi-urban areas apart from the slums and dwellings in the urban areas. The education and training of various levels of medical, paramedical, and nonmedical personnel involving medi/rehab care programs is a formidable task. Inspection, approval, and accreditation of various levels of centers are intricate tasks. The authorities concerned must have a clear concept of the basic infra-structural requirements for establishing these centers.

It is not difficult to regulate, standardize, and accredit at higher levels, namely, doctoral, master's, graduate, and diploma levels. However, in these underdeveloped and developing nations, the human resources potential of the less affluent, who form 80% of the population, poses the challenge to those who provide leadership in integrated interdisciplinary areas like clinical engineering, rehabilitation engineering, health-rehabilitation care (HRC) technology, and paramedical education. Many intelligent teenage boys and girls living in the rural and semi-urban areas after their 10 or 10+2 courses cannot afford migration to cities and towns to study in hostels and continue education. Many of them have aptitude and are intelligent. Various levels and types of necessary paramedical personnel have been identified. Some of these can be located in the semi-urban and rural areas to the benefit of humanity and society. In the last decade, attempts have been made to regulate the education-training aspects of this cadre in a planned way by regulating such items as the curricula, course duration, and fee structure.

The Need for Health Sciences Technology Education and Training

- Human resources potential must be developed based on the needs in urban, semi-urban, and rural areas.
- Socioeconomically backward children who are talented, after their 10 or 10+2 courses, must get an opportunity to nurture and harness their potential based on their aptitude.
- It becomes mandatory in all democratic nations to provide education and training at reasonable costs.
- It is most desirable to locate these centers in the semi-urban and rural areas as far as is feasible.
- Considering the affluence of 10–15%, medical engineering education is beyond the reach of the majority of talented youth. Even merit seats are not accessible in view of the escalating fees.
- Capitation/management seats in engineering, medicine, nursing, pharmacy, and dental are almost exclusively meant for the very highly affluent.
- Considering the sad and pathetic situation after more than 50 years of Indian independence, strategies must be evolved to improve the knowledge base and placement potential of those who are less fortunate.
- Health sciences technology education and training at the graduate level (6 semesters + 2 of internship) as initiated by the Sri Ramachandra Medical College and Research Institute (SRMC & RI) at Chennai could serve as a model for similar programs at selected medical institutions all over the nation. Such a course is within the reach of some in the middle-income group.

Role of Clinical Engineering Centers

Clinical engineering centers throughout the nation share the goals listed below:

- To train various levels of personnel to operate, maintain, and repair all types of hospital equipment
- To encourage innovation, initiate design, and fabricate simple-use diagnostic, therapeutic, and bio-analytical devices and rehabilitation devices and appliances
- To enlighten and educate concerned medical, paramedical, and nonmedical personnel about various systems of medicine and techniques
- To initiate planned scientific steps to optimize manpower material utilization utilizing the latest management techniques
- To promote closer interdisciplinary interaction among clinical, biomedical, paramedical, and nonmedical personnel by periodic seminars and short-term courses in various clinical areas
- To maintain close relations and strong interaction with the Clinical Engineering Division of the International Federation for Medical and Biological Engineering (CED IFMBE)
- To initiate and introduce concepts of health care and rehabilitation care technology planning, coordination, management, and administration, and to attempt their application at all levels of hospitals and medical institutions under governmental and voluntary agencies
- To set up the National Clinical Engineering Certification Program in association with the All India Council for Technical Education–Continuing Education Programme (AICTE-CEP) in Bangalore
- To plan and organize awareness programs at various centers all over the country with the cooperation of local medical, paramedical, and nonmedical personnel under the guidance of biomedical specialists sponsored jointly by AICTE-CEP and the Clinical Engineering Centre (CEC) in Bangalore
- To promote joint projects with other global nationals in the fields of clinical and rehabilitation engineering, and sponsor younger colleagues to update their knowledge
- To promote wider utilization of the wide range of useful therapeutic techniques whose clinical efficacy is proven
- To help set up feasible and economically viable integrated therapy centers in the rural and semi-urban areas under governmental and voluntary agencies
- To help improve the quality of care at all levels using the latest interdisciplinary advancements, in cooperation with state Medicare authorities

Technology Management in Health Care Delivery Systems

A dynamic, innovative, interdisciplinary, integrated-planning, coordination, management, and administration approach is essential, in order to manage the health care delivery systems in a cost-effective manner in the urban, semi-urban, and rural areas. Improving the quality of medical rehabilitation care of 1020 million people with 100 million handicapped and 50 million elderly along need-based, time-sensitive, realistic, feasible lines poses a formidable techno-bio-psycho-socio-medical challenge to all who are genuinely committed (see Table 78-1).

Obviously, in a unique, multilingual, multireligious nation like India, it involves very close interaction among specialists of various disciplines in the fields of medicine, engineering, sciences, and technology. The actual needs in the urban, semi-urban, and rural areas must be evaluated depending on the local situation. A wide range of parameters must be considered in order to optimize the utilization of the large manpower pool, reasonable material resources, and limited funds. Human and medical ethical aspects must be considered while adapting automation and semi-automation techniques. Humanism and optimism are to be integrated with action. There is an urgent need to evaluate in a planned scientific way the clinical diagnostic and therapeutic potential of various systems of medicine and the wide range of techniques. As part of continuing medical

Table 78-1 Health rehabilitation care data for India

Population	1020 million
Handicapped	100 million
Elderly	50 million
Medical colleges (attached hospitals with 500-1000 beds)	175
Major hospitals (500 and above, up to 2000 beds)	1500
Referral centers of clinical excellence (100–500 beds)	200
Specialist medical institutions	100
District level hospitals (150–300 beds)	550
Rural hospitals/community health centers (30–100 beds)	2,500
Primary health centers (5–10 beds)	30,000
Community health sub-centers	150,000
Bed-to-population ratio	1:1300
Total number of hospital beds	800,000

education (CME) programs, awareness workshops, short- and long-term training and education, refresher courses must be planned and organized in medical colleges, hospitals (district level upward), and in centers of clinical excellence. Medical, paramedical, and nonmedical personnel at various levels must be exposed to these programs in order to update their knowledge base and to improve their placement opportunities. Funds alone can never improve the quality of health care delivery systems. Dedication and commitment, coupled with optimism and humanism, are the basic fundamental prerequisites to improve the quality of care at various levels. Some of the topic areas are identified in Table 78-2. These topics deserve consideration for integration into awareness/training programs.

The devices and systems listed in Table 78-3 integrate low-cost, medium-cost, high-cost, and low-tech, medium-tech, and high-tech equipment and systems used in day-to-day work in all levels of hospitals (i.e., from primary health centers to centers of clinical excellence). The above exclude high-cost, high-tech systems used in medical research and development.

Optimizing Equipment Utilization

Optimizing the utilization of medical devices requires an understanding of the principles of operation and the underlying medical condition being diagnosed or treated. Table 78-4 lists the subjects covered in the course *Optimizing Equipment Utilization in Medical Institutions*.

Paramedical Education and Training

Overview of Centers of Certificate Programs

1. The prerequisite for one-year certificate programs is Pass in 10 or 10 + 2 who have aptitude.
2. The majority cannot afford medical, engineering, dental, nursing, pharmacy, and physiotherapy courses.
3. The development of human resource potential is a challenge to all who are involved in this significant task.
4. Inspection, approval, and accreditation aspects have been regulated and standardized for higher levels, namely doctoral, master’s, degree, and diploma.
5. The cadre of clinical assistants/health care technicians form the second line to assist those such as trained nurses, physiotherapists, ECG and X-ray technicians.
6. This cadre is meant for those students who are intelligent and show aptitude, but who are not affluent enough to enroll in higher-level courses.
7. Development of this cadre is bound to improve the quality of medical/rehabilitation care all over, especially in the semi-urban and rural areas, making it cost- effective and accessible to the nonaffluent millions.
8. Certain minimal infrastructure in the form of classrooms libraries, laboratories, and technical staff (both full-time and part-time) are needed. These centers can be graded depending on such factors as location and training facilities.

Table 78-2 Health care technology management topics

Health care delivery systems development	Health care delivery systems management
Predictive, preventive, curative maintenance aspects	Safety, standardization, calibration
Hospital communication systems	Critical care areas management
Air- and water-quality monitoring	Blood bank and clinical laboratory services
Imaging-techniques systems	Trauma-center management
Organ-transplant techniques management	Computers in medicine
Impact of internet and multimedia	Yoga, naturopathy, meditation
Integrated-therapy approach	Dental-care systems
Energy management and audit	Hospital waste management and disposal
Essential hospital engineering services	Human resources management
Basic hygiene and cleanliness	Prevention of infection
Rehab management of elderly and handicapped	Mobility, transport, accessibility aspects
Human engineering management	Intra-ocular lens implantation
Holistic systems management	

Table 78-3 Equipment and systems routinely used in hospitals for medical diagnosis, analysis, and therapy

Diagnosis	Bio-analysis	Therapy	General purpose
Electrocardiographs	Microscopes	Pacemakers	Cold chain
Electromyographs	Centrifuges	Defibrillators	Refrigerators
Electroencephalographs	Autoclaves	Ventilators	Sterilizers
Audiometers	Incubators	Heart-lung machines	Heaters
X-ray units	P.E. Calorimeters	Resuscitators	A.C. Units
Sonographs	Flame photometers	Stimulators	Hospital communication systems
CAT Scan	Spectrophotometer	X-ray units	UPS systems
MRI Scan	pH Meter	Cobalt therapy unit	RP systems
Blood pressure apparatus	Electrophoresis	Linear accelerator	Emergency
Stethoscope	Chromatographs	Physiotherapy	Generators
ICU Setup	Gas analyzers	Dialysis units	General and OT
CCU Setup	Ovens	Hearing aids	Lighting
Polygraphs	Water quality	Speech correction	Fans
Transducers	Analyzers	Devices	Computers
Recorders	Auto analyzers	Ortho-Pros implants	
CCTv	Tissue processors	IO Lenses	
Catheterization lab	Radiation safety	Anesthesia apparatus	
Bio-telemetry	Setup	Radio isotopes	
Endoscopes	Glassware	Behavior therapy	
Computerized TO	Reagents	Electronarcosis	
Diagnostic systems	Blood banks system	Traction units	
		Rehab. aids and appliances	

9. About 60 of the 125 centers are located in Kerala, where missionaries pioneered paramedical education in Asia. Some of them have been functioning for the last two to three decades. Most of those trained are now employed all over the world.
10. Any new center needs a gestation period of at least 3–5 years to overcome the initial teething difficulties, bottlenecks, handicaps, barriers, and hurdles for its survival and eventual development.
11. There is an urgent need to regulate and standardize the duration, curricula, fee structure, staff pattern, and laboratory facilities. Thus, under AICTE-CEP, Ministry of Human Resource Development, the Paramedical Council of India should be instituted along the lines of the Nursing Council, Pharmacy Council, Dental Council, Rehab Council, and Medical Council for ensuring quality of education and training.
12. The twin purpose of improving the knowledge base and enhancing placement potential can be achieved for all of those younger colleagues who are not able to afford higher levels of education.

Interdisciplinary Approach

Interdisciplinary areas involve a close integration of a wide range of diverse disciplines. One outstanding example is the field of health rehabilitation care technology, which encompasses biomedical engineering, clinical engineering, rehab engineering, and complimentary medical systems and techniques. Training of competent faculty required for the certificate, diploma, degree, post-graduate, and doctoral levels is a formidable challenge. Various branches in the fields of medicine, engineering, science, technology, sociology, and psychology are integrated to meet the preventive, diagnostic, therapeutic, and research aspects that pertain to the well-being of the individual. Safety, standardization, calibration, operation, and maintenance are parameters that must receive appropriate attention. Yoga, naturopathy, and meditation play a vital role in augmenting the efficiency of various systems of medicine and a wide range of techniques utilized to relieve pain and suffering. Treating elderly and handicapped patients involves mobility, transport, and accessibility aspects. Dynamic leadership is essential to conceiving and evolving realistic and feasible programs to suit the needs of the medical fraternity at various levels. One can visualize the teamwork that is required in order to achieve time-sensitive targets. Approval and accreditation of these need an unbiased approach to ensure quality care at all levels. Courses must be developed in accordance with the needs of their participants.

Table 78-4 Optimizing Equipment Utilization in Medical Institutions course content

Basics of medicine–clinical anatomy	Maintenance aspects
Basics of medicine–clinical physiology	Safety aspects
Basics of medicine–clinical biochemistry	Standardization/calibration aspects
Medical diagnostics	Anesthetic techniques
Bioanalytical techniques (e.g., blood bank)	Imaging techniques
Medical therapeutics	Health rehabilitation care technology
Cardiological techniques	Clinical engineering overview
Neurological techniques	Institutional wastes disposal
Nephrological techniques	Institutional energy management
Oncological techniques	Refrigeration and air conditioning
Otolaryngological techniques	Institutional communication systems management
Prosthetics–orthotics	Operation theater planning
Biomaterials and biotransducers	

Table 78-5 Certificate-level technician courses at the All India Council for Technical Education—Continuing Education Programme in Bangalore (AICTE-CEP)

Medical laboratory technology	Clinical engineering
Physiotherapy	Rehabilitation engineering
Integrated therapy	Anesthesia
Blood bank	Hospital waste management
Imaging technology	Energy management
Dialysis	Communication systems
Operating theater	Computer operation
Electrocardiography	Biomaterials
Electroencephalography	Sonography
Ophthalmology	Medical transcription
	Audiometry

In the final lap of any interdisciplinary program, due weight must be given to the aptitude of the trainee, namely whether the trainee opts for (1) research; (2) development; (3) operation and maintenance; or (4) safety standardization and calibration. It is obvious that all of these involve integration of CME, continuing education programs (CEP), and quality-improvement program (QIP) aspects. It will be impossible for training institutions to equip with a very wide range of diagnostic and therapeutic systems. They will need to find professional support from medical institutions and hospitals to expose trainees to the day-to-day use of equipment and systems. The faculty must be unique, service-minded, humanistic, and optimistic in their approach. In addition to regular programs, various levels of workshops, seminars, and symposia must be organized in medical institutions and hospitals, to update knowledge. Improving quality of care involves such topics as waste-management, safe blood supply, energy audit, and accident emergencies. This note highlights salient features involved in developing curricula for courses of various levels.

Health Scenario

India is the largest democratic nation in the world. Its population exceeds one billion and includes 100 million handicapped and 50 million over age 62. India is also unique because it integrates a multilingual, multi-religious population. Affluence is around 10–15%, and nearly 80% live in the rural areas and in slums and dwellings located in the urban and semi-urban areas. One can visualize the major challenge facing all of those genuinely involved interdisciplinary intellectuals who obviously must provide the much-needed innovative initiative and dynamic leadership under such circumstances. It is bound to be a feasible, realistic, need-based, and time-sensitive approach involving optimization of the large pool of trained and untrained manpower. Reasonable material resources, and very limited monetary resources, are available for health rehabilitation care programs. A techno-bio-psycho-socio-medical teamwork approach appears mandatory if the quality of health rehabilitation care is to be improved at all levels, especially in rural areas, where the majority of the socioeconomically deprived persons live.

Health Care Technique

Preventive, diagnostic, analytical, and curative aspects of medi/rehab care involve a wide range of techniques that, in turn, involve various levels of instrumentation. The recurring and nonrecurring costs involved depend on the level and quantity of the high-tech, medium-tech, and low-tech instrumentation required. A wide range of parameters like location, manpower, material facilities availability, disease pattern, and required funds play decisive parts. Health/medicare delivery is the responsibility of concerned state governments, ably augmented by voluntary organizations. Broadly, a three-tiered approach starting from the grassroots level, i.e., primary health center through district-level hospitals to major hospitals or specialist referral centers. Complementary systems of medicine, namely Ayurveda, Unani, homeopathy, Siddha, and a wide range of techniques under energy medicine, including yoga, meditation, and naturopathy, are slowly but surely finding wider acceptance, on both national and global levels. Safety, standardization, quality, and reliability are to be evaluated and assessed periodically in a planned scientific way, to ensure optimized medi/rehab care at low to moderate costs to the nonaffluent millions.

Human Resources Development—Education and Training

Human resources development is the basic and fundamental objective of all CEP and QIP programs initiated by the AICTE, International Society for Technology in Education (ISTE). Agencies like University Grants Commission (UGC), Council of Scientific and Industrial Research (CSIR), Indian Council of Medical Research (ICMR), Department of Science & Technology (DST), Medical Council of India (MCI), New Anglican Missionary Society (NAMS), World Health Organization (WHO), United Nations Education, Scientific and Cultural Organization (UNESCO), United Nations Children's Fund (UNICEF), UNDP, World Bank, Ford Foundation, Voluntary Health Association of India (VHAI), Christian Medical Association of India (CMAI), and The Institution of Electronics and Telecommunication Engineers (IETE) augment the efforts of AICTE-CEP and ISTE. Medical diagnosis and therapy is mainly based on qualitative and quantitative analytical laboratory clinical examination results. Paramedical or surgical intervention, followed by medical or surgical intervention, followed by a medical or surgical procedure, followed by post-medical/surgical corrective procedure, involves utilization and application of paramedical techniques provided by trained paramedical specialists and technicians. All of these depend on instrumentation that is low-tech, medium-tech, and high-tech, of low-cost, medium-cost, or high-cost, depending upon the clinical parameters to be analyzed. Paramedical technicians form the fundamental base of any medical or surgical diagnosis therapy. Education and training of this cadre is essential. Autopsy of 50 years of human resource center development (HRCD) programs, and biopsy of the present will be

the pointer for overcoming past barriers, bottlenecks, and hazards in planning for the future. Technology needs at various levels are to be assessed and developed. Certain mandatory measures might be inevitable, to improve the quality of medi/rehab care on a cost-effective basis. Accountability is the basic and fundamental necessity. Implementation of recommendations at various levels is most urgently needed and must be a top priority.

As in the other areas, trained-manpower needs require a realistic, need-based, feasible, time-sensitive, and cost-effective approach. Integrated interdisciplinary education forms the basis of any paramedical education or training program. The mode of delivery is by way of organizing awareness, seminars, symposia, and workshops to be followed by short-term and long-term courses, six-month or one-year certification courses on selected and relevant topical areas. The number needed depends on the type of center, namely primary (PHC), secondary (district level) or tertiary (major and referral centers). Referring to Table 78-7, at the PHC, one can utilize 1–4, at the secondary center, 1–7 and 12–17, and at major hospitals and referral centers, 1–18. Nursing assistants and pharmacy assistants are needed in larger numbers to assist trained nurses and pharmacists who complete courses (degree or diploma). It is estimated that every trained nurse or pharmacist needs three or four assistants to assist them in their work. Therefore, placement-oriented, knowledge-based courses, which form a major part of AICTE-CEP objectives, will be fulfilled. It is also part of the strategy for the development of human resources, especially in semi-urban and rural areas. It also helps to narrow the widening urban and rural knowledge and placement gap. Governmental and voluntary organizations can make use of such technicians. The AICTE-CEP is approving paramedical courses after due inspection of such centers that are offering these courses. To date, nearly 100 centers have been approved. It is most heartening that a majority of them are located in semi-urban and rural areas to benefit the socio-economically needy, who are educated up to 10th standard or 10 + 2 level and could not continue because they are unable to pay the capitation or donation demanded by nursing schools and colleges and colleges of pharmacy. Physiotherapists also are needed in large numbers. A broad-based, open-minded, integrated, interdisciplinary teamwork approach is needed at all levels. The course-fee structure must be flexible to allow the training institutions located in rural areas to charge less for the needy and female trainees. Lack of funds should never block talented rural students from rising up and helping to close the urban–rural technology gap. Paramedical courses play a vital role in improving the quality of life of the nonaffluent millions in rural areas, by promoting human resource development (HRD) and utilizing CEP of AICTE. A review of the past 50 years of education and training in this field is a worthwhile exercise, followed by a study of the present, to apply corrective measures. One can get a meaningful glimpse of the reality of the situation only when one visits rural areas. Such visits leave one feeling sad but with hopes for a better decade by educating and training rural youth.

Outstanding medical specialists, along with equally reputable health rehabilitation care (HRC) technologists, are part of the Board of Examiners, which is headed by an internationally renowned humanist neurosurgeon and assisted by a dynamic secretary, who plans and conducts theoretical and practical examinations at centers approved by AICTE-CEP. Currently, courses on medical lab technology, nursing assistants, physiotherapy, X-ray, and ECG have been approved depending on the institutions' requests, after due inspection of their facilities. More courses listed might become acceptable as the national and global placement potential improves. It is most heartening that quite a number of those trained have found, and are finding, gainful openings all over the nation, and overseas. It augurs well for both the trainees and approved institutions, and they can be optimistic.

Holistic Approach to Health Rehabilitation Care—Challenges in the Millennium

The ever-escalating modern Medicare costs make it mandatory and imperative to explore alternate approaches to evolve strategies to develop an integrated interdisciplinary holis-

Table 78-7 The Need for Paramedical Education and Training)

1. India's population exceeds one billion, with nearly 10% handicapped and 3% elderly. Affluence is around 10–15%, and nearly 80% live in rural areas.
2. In the above context, one must conceive and evolve strategies for education, training, and development of an enormous human resource potential, to improve the quality of life, especially in semi-urban and rural areas.
3. Unfortunately, prevalent socioeconomic conditions force a large number of intelligent students to seek paramedical education and training after their 10 or 10+2 courses. Paramedical courses began almost 30 years ago in India, especially in Kerala.
4. About 3 years ago, AICTE-CEP initiated steps to constitute a board of examiners in this area, with a view to standardizing a syllabus, duration, and basic infrastructure facilities. The normal procedure is to inspect and approve those who meet the basic conditions.
5. Broadly, about 20 types of technicians have been identified, considering present and futuristic placement potential.
6. Three levels of technicians are needed, starting from the primary, grassroots level and moving to the secondary district level and final tertiary level of city hospitals. Twin targets of improved knowledge base and better placement can be achieved.
7. Approval, assessment, accreditation, and QIP, have received attention at the post-doctoral, doctoral, master's, graduate, and diploma levels.
8. It is only apt, as part of HRD, CEP-AICTE develops human resource potential in semi-urban, rural areas by educating and training youth. It must be a missionary effort.
9. The 26 nodal CEP Centers can initiate steps to plan, coordinate, promote, and propagate paramedical education throughout the nation.
10. By these measures, the poor can have an opportunity to harness their potential, based on aptitude. A gestational period of three years is inevitable before one can assess, evaluate, standardize, and accredit these need-based, cost-effective, paramedical training centers.

Table 78-7 Paramedical personnel clinical assistants required (ranked according to demand)

NOTE: 1 to 4 PHC Level (grass roots); 1 to 7 & 12 to 17 (district level); 1 to 18 major hospitals & referral centers.

tic approach. This must be cost-effective, need-based, realistic, feasible, time-sensitive, and target-oriented. Optimizing utilization of the large manpower pool, limited material resources, and very limited monetary resources is the most urgent need. The health rehab care of nearly one billion people, with 10% handicapped and 3% elderly, is a formidable techno-bio-psycho-socio-medical challenge.

Integrated therapy centers, using an open-minded, broad-based, holistic approach, are the only hope for improving the quality of medi/rehab care of the nonaffluent millions in India. Urban, semi-urban, and rural health rehabilitation care requires a planned, scientific approach. Fortunately, a wide range of noninvasive techniques and alternate systems of medical care, namely Ayurveda, homeopathy, Unani, and Siddha, are available for wider utilization. Yoga, naturopathy, and meditation care augment any system of medicine, thus reducing the medical care costs. A holistic medical care approach with integrated therapy appears to be the only hope for the nonaffluent millions in third-world nations, where two-thirds of the world's population lives.

One sincerely hopes that the coming decade will see the emergence of the holistic care to benefit humanity. Karmayogis who are optimists with humanism as the base are the answers.

Conclusion

Attempts must be made to modify and to adapt the techniques of yoga, naturopathy, and meditation into everyone's day-to-day life whether in the urban, semi-urban, or rural areas. Selected yogasanas, pranayama, and meditation for about 30 minutes daily, coupled with modified naturopathy practices to suit the practical daily life, can go a long way in enabling wider utilization by all sections of the people in society. There is a most urgent need to evaluate the percentage of people who practice them every day. Agencies like National Institute of Naturopathy (NIN), Central Council for Research in Yoga & Naturopathy (CCRYN), and Indian Systems of Medicine & Homeopathy (ISMH) can initiate steps to get a glimpse of the present status, so that they can plan for the future. Table 78-8 in the Appendix lists leading yoga, meditation, and naturopathy research/training/education institutions in India. One must evolve strategies to develop a feasible, holistic approach. Outstanding yogacharyas, naturopaths, and meditators have undergone modern medical/surgical procedures when cardiac, neurological, and orthopedic intervention becomes inevitable to provide relief from pain and suffering. Birth and death are accepted realistically.

In addition to those institutions listed in Table 78-8, scientists in the National Institute for Mentally Handicapped, Secunderabad (NIMHANS), Defence Institute of Physiology Allied Sciences (DIPAS), Institute of Nuclear Medicine & Allied Sciences (INMAS), All India Institute of Medical Science (AIIMS), MAMC, Jawaharlal Institute for PG Medical Education & Research (JIPMER), Post Graduate Institute for Medical Education & Research (PGIMER), India Institute of Technology (IITS), India Institute of Science (IISc), and physiology departments of some of the medical colleges are actively involved in planned scientific evaluation of the technique. Some university yoga departments are conducting research. UGC plans to help universities to set up yoga centers. Agencies like the Department of Science and Technology of India (DST), Indian Council of Medical Research (ICMR), CCARYN, Defence Research & Development Organisation (DRDO), and UGC are supporting these projects.

"Think globally, act locally, coupled with simple living and high thinking" should be our motto.

Section VII

Medical Devices: Design, Manufacturing, Evaluation, and Control

Gary H. Harding

Greener Pastures
Durango, CO

Alice L. Epstein

CNA HealthPro
Durango, CO

The authors of the next chapters provide historical and contemporary insights into many aspects of the history, design, manufacturing, costs, and control of medical devices from a clinical engineering perspective. These chapters begin with the evolution and growth of medical device technology, from the early healer's use of sharpened stones to endoscopy, and through the intricate financial aspects of technology acquisition, software development, and the excitement of research and design of new, cutting-edge technology. These chapters examine issues that face medical device manufacturers, as well as hospital-based engineers, innovators, designers, testers, and evaluators. They share interests, concerns, and issues and address them with an interest in providing insight into the information that will prove valuable to a clinical engineer, regardless of the base from which the design, manufacturing, or control is performed.

Richter provides a thoughtful review of the evolution of medical device technology, noting the contributions of Hippocrates, Santorio, Galileo, and others, with specific emphasis on the importance and interface of temperature measurement, bioelectric signals, blood pressure, pain relief, imaging, and patient monitoring. Richter provides support for the concept that man-made technical innovation influences human biological evolution and that the physician-engineer relationship will continue to strengthen and expand.

Gaev notes that with more than 5000 different types of medical devices on the market, it becomes almost impossible to have medical intervention without the application of a device. He provides a basic overview of the leading clinical maladies that affect the world population and the expenditures that are made worldwide to address these maladies. Gaev poses the question of allocation of health care spending and the relative success in treating illnesses and injuries. His examination of modalities to treat same clinical morbidities includes an example of treating diabetic patients to help understand the various ways in which diagnostic and therapeutic devices come into play as a result of the clinical course of a disease.

Canlas et al. provide a glimpse into the actual clinical engineering practices at William Beaumont Hospital (Michigan) with respect to technology management within the hospital setting. The authors bring to the forefront the importance of a systems approach to technology management, including ensuring medical device safety through participation in equipment selection and evaluations. They review the need for continued vigilance in the evaluation of technology after product selection, including cost-effectiveness review, anticipation of future technology needs, evaluating designs for efficacy and reliability, and occasional prototype design and redesign.

Oberg discusses the nuances of device innovation, beginning with research and design, providing insight into invention, patents, product life cycle, publishing, and actual device development. Oberg believes new product ideas should be put through a rigorous assessment process when evaluating effective product development. Market analysis, technology assessment and economic assessment should preface concept testing and prototype development. Oberg examines the way that commercial exploitation through licensing and starting new companies for commercialization of a product typically progresses.

Hyman and Wangler examine the ways in which human factors considerations affect safe and effective use of medical devices in the actual health care delivery setting. They discuss human factors in the context of all devices in use, physical environment of use, and the personnel using the device. The authors acknowledge the importance of the differences in people (e.g., vision, hearing, and height.) device interactions, the multiple patient environments relating to the physical environments, and the incalculably

important issue of personnel. They note that all human factor-related interventions might not be successful unless there are adequate management and resources, and they believe that this should include a nonpunitive system of adverse and near-miss event reporting with a focus on investigations to provide safeguards within the health care delivery system.

Geddes sets a paradigm of failure modes by types of medical devices; diagnostic, therapeutic, and assistive/rehabilitative. A brief explanation of product liability that is specific to product defect, misuse, negligence, and design defect is presented. Accidents relating to the three types of medical devices are explored through specific examples.

Fries and Bloesch address the burgeoning issue of software-intensive medical devices. They provide lessons and an organized approach to specifying software requirements, creating software design through implementation. Elements of software development include identification and review of existing software standards, evaluation of design alternatives, and tradeoffs to determine the software architectural model. The authors note the importance of selecting effective design methodology and programming language from a realistic framework. Fries and Bloesch explore the relationship of software risk analysis and metrics based on the types of hazards identified, speculation as to the way the equipment can fail, and what failure is tolerable. Design review, performance predictability, design simulation, verification, and validation all lay the groundwork for implementation.

Keller details the ECRI (Plymouth Meeting, PA) method of comparative evaluations of medical devices. He notes the importance of identifying equipment needs, technology alternatives, and any other specialties that might benefit from the proposed equipment prior to the device evaluation. ECRI's model uses a rating system of acceptability, based on essential features. The model includes a detailed comparative evaluation that is based on a pre-established set of comprehensive criteria. Keller lists examples of critical criteria, including performance and safety, human factors, construction quality, vendor service, and cost. He provides a discussion of ways to address findings, noting the importance of the evaluator's consideration of the relative importance of various aspects (e.g., performance, safety, and ease of use) of the evaluation.

Balar examines the process of evaluating investigational devices in the clinical setting by providing insight into the ways in which clinical engineers at William Beaumont Hospital (Michigan) evaluate such devices for their Institutional Review Board (IRB). The author explains the role of the clinical engineer's in evaluating the safety and efficacy of investigational devices used in research studies. There are discussions of the evaluation process, from initiation through research, risk analysis, and reporting. Tips for overcoming obstacles in this arena are presented.

After reading this section, clinical engineers will gain some understanding of specific issues that must be considered in medical device design, manufacturing, and control as it relates to clinical engineering. Useful personal insights by professionals who are the clinical engineer offer the benefit of experience and the lessons learned through applied research. The complexity of medical device design, manufacturing, and control becomes apparent through the eyes of these experts, all of whom understand that the future might be even more complex. Stressing the importance of knowledge, systems, and clinical engineering participation and support, medical device design, manufacturing, and control can be performed safely and effectively to the benefit of patients, medical professionals, and others.

Evolution of Medical Device Technology

Nandor Richter

ORKI

Budapest, Hungary

The Origins

In the early phase of civilization, instruments were used in medical treatment. Healers used sharpened obsidian stones for skull trepanation, and metal knives later became common tools. Thousands of years ago doctors sought to cast a glance into the human body. They tried to observe the inner structure and the functioning of the living organ through the mouth, the rectum, and the vagina. Observation through these parts caused minimum functional disorder, and minimal tools were needed. Around 400 BC, Hippocrates was the first to mention the endoscopy when he described a rectum examination. At that time, a light source was not yet available. Around AD 1000, the well-known Arab doctor Abu al-Quasim used a glass mirror for vaginostomy. Because of inaccurate notions and the lack of measuring instruments, observations could lead to only rough conclusions.

The Enlightenment brought with it a significant impetus as the dogmatic, retarding forces of the Middle Ages influenced scientific activities less and less. During the seventeenth century, the exact sciences developed vigorously. The curious human examined and understood nature better and more objectively. Progress in healing required the increasing application of tools and equipment. For example, doctors realized rather early the importance of body temperature and its fluctuation. Again, it was Hippocrates who considered body temperature as the most important sign in the case of acute illnesses. However, it was not until around 1612 that the Italian doctor Santorio made the first clinical thermometer. He is also credited with the introduction of the weight balance and hygrometer. With these devices, the desire of Galen (131–201 AD), that not only the type of illness be identified but also the “quantity” of the illness should be measured, could now be realized. Galileo stated “measure the measurable and make measurable what was not measurable till now.” His words are equally important and basic even today. One can apply this to all diagnostics and to most medical equipment.

Temperature Measurement

Thermometers have been enormously helpful to physicians. Time series of temperatures were made possible, providing information on the progress of an illness and the trend of the patient’s condition. One good indicator of the importance of the thermometer is that over one billion temperature measurements are carried out yearly in the hospitals in the United States.

Physicians looked for symptoms that could increase their knowledge about the condition of the patient, the nature of illness, and its seriousness. Besides temperature, the color of the face, the color and odor of urine, and the rhythm of the heart were all peculiar and perceptible to the patient. It was desirable to measure these parameters quantitatively and not simply to observe the color of the patient’s face. Quantifying color, heart rhythm, and chemical composition of urine had to wait for further developments in the chemical and technical sciences.

Bioelectrical Signals

The discovery of bioelectrical signals was of paramount importance in that it led to diagnostic and therapeutic applications. Today, we know that bioelectrical phenomena are characteristic of all living organisms. Long before bioelectricity was well understood, much was already known about the electrical activity of nerves and muscles. Platon (427–347 BC) mentioned electric rays (torpedinidae) found in the Mediterranean Sea. Aristotle (384–322 BC) also wrote about these marine creatures. He mentioned that touching these rays could cause deafness. In the eighteenth century, Aloisius Luigi Galvani (1737–1798), a professor at the University of Bologna, performed experiments on frog nerve-muscle preparations. He stimulated with electrical charges the nerve that led to the frog’s femur and found that during stimulation the femur muscle contracted. In one of his experiments, he demonstrated the cell membrane potential, the polarizing potential of cells in rest. For his achievements, Galvani was named the father of electrophysiology. From that time onward, an increasing number of scientists started to study the action potentials generated in living organisms.

These electrical signals are primarily the cell membrane potentials, action potentials of heart and muscles, and the action potentials of the brain. Studying action potentials requires sensitive equipment and thorough knowledge in measuring technique. Depending on the source of their origin, the amplitude and frequency domains of these signals are significantly different. From the point of view of measurement technique, the heart action potentials, the ECG waves, can be considered as the easiest to measure. Voltage potentials of these signals are in the millivolt (mV) range, their useful frequency domain is 0.1–100 Hz. Brain action potentials are on the order of microvolt (μV) and the frequency domain is 0.1–10,000 Hz. Evoked potentials are even lower with a frequency range of approximately 10–10,000 Hz.

Around 1856, electrocardiographic signals of a frog’s heart were measured for the first time. In 1903, Willem Einthoven (1860–1927) introduced his string-galvanometer and recorded ECG signals. Hans Berger started to study the electrical signals of the brain by electroencephalograph measurements in 1924. However, his first good-quality electroencephalogram was not ready until 1929. In 1943, Weddel succeeded in registering muscle action potentials with an electron beam oscilloscope. But the first commercial electromyograph did not enter the market until around 1960.

Blood Pressure

Aware of the importance of blood circulation, studying blood pressure was a natural requirement. In one of the first experiments, a tube was inserted into the neck artery of a horse, and the pressure variation generated by the heart was measured. For human application, the bloodless measurement of blood pressure was a necessity. However, one had to give a measurable, practical definition of the blood pressure. There was no simple, bloodless way of measuring the instantaneous value of blood pressure until the introduction of the systolic-diastolic measurement. Still accepted in daily routine, this detection technique is based on the Korotkoff sounds. Digital technology made small blood pressure meters possible with a concomitant surge in their use in the home as well as the hospital.

Anesthesia and the Relief of Pain

Horace Wells, an American dentist, performed the first painless dental operation in 1844. He used nitrous oxide, known also as “laughing gas.” Therefore, he is considered the inventor of narcosis. Anesthesia, the painless operation on patients, was an immense development in surgery. It gave enormous push to the development of surgical instruments and apparatuses used in operating rooms and beyond.

It is also interesting to draw attention to a different medical advance, acupuncture anesthesia. Western medicine is learning more and more about this practice of traditional Chinese medicine. While its mechanism is still not completely known, it does prove useful in certain areas of anesthesia.

X-ray and Nuclear Medicine

The desire of physicians for centuries to be able to look into the human body was finally realized in 1895 with Conrad Roentgen’s discovery of X-rays. In the following century, the application of X-rays to diagnosis and therapy gave strong momentum to the advance of medicine. In hospitals and clinics, the medical applications of X-rays became a separate professional field. With the development of the engineering sciences and, later, informatics and computer techniques, application of the images generated by X-ray increased. Of course, this went along with the construction of more sophisticated equipment. Therefore, the demand increased for experts who are familiar with the operation and maintenance of these devices.

Imaging and Image Processing

X-ray images, with their increasingly fine details, provided increasingly more information. Image intensifiers and video monitors rendered possible the manifold applicability of X-ray equipment. High-power and fine-resolution X-ray tubes expanded further the application possibilities. X-ray equipment, such as the tomograph, angiograph,

angio-cardiograph, and the urograph, was developed for special applications. Imaging and image-processing methods provided the information-enhancing possibility for physicians.

CT and MRI

In the field of imaging, the computer tomograph (conceived by William Oldendorf and developed by Godfrey Hounsfield and Allen Cormack) brought revolutionary change. The first successful clinical experiments occurred in 1972. The Nobel Prize was bestowed upon the two inventors in 1979, and Godfrey Hounsfield was knighted in 1981. The basic idea of computer tomography went beyond X-ray imaging. The principle is also becoming important in fields where the source is non-ionizing radiation.

The basic phenomenon of magnetic resonance imaging was first observed in 1946. Certain atomic particles in strong magnetic fields absorb very high-frequency electromagnetic waves selectively. Particularly those nuclei in which at least one proton or one neutron is unpaired show this phenomenon. This absorption can be measured and evaluated. In the human body, water and lipid (fat) molecules, which contain hydrogen, show the effect in measurable magnitude. This noninvasive, relatively hazard-free diagnostic method is based on this selective absorption phenomenon. The first MRI equipment was put on the market during the early 1980s. Since then, its application has become broad including, among others, the study of the brain, breast, heart, kidneys, liver, pancreas, and spleen.

Nuclear Medicine

The use of radioactive isotopes as tracers by George C. de Hevesy in 1912 was a great epoch-making discovery for which Hevesy was recognized with the Nobel Prize in 1943. Wide-ranging application of radioactive tracers became possible after World War II. Radioactive isotopes came to the market after the 1950s. Around this time, development of the equipment necessary for measurements was completed as well. Importance of manmade scintillation crystals was extraordinary. These crystals make possible the detection, counting, and measurement of the radiation emitted from disintegrating nuclei. The development of synthetic crystals, the electron multiplier, and spectrum analyzers altogether resulted in the general application of nuclear-measuring technique in health care. In the following decades, the evolution of imaging and image-processing technology further broadened the field of nuclear measuring techniques. The introduction of the gamma camera made possible the imaging of larger parts of the body.

Ultrasound

In 1880, Madame Maria Sklodowska Curie and her husband Pierre discovered radium and subsequently received the Nobel Prize. Pierre's brother Jacques discovered the piezoelectric effect. When high-frequency electric fields are imposed on a piezoelectric material, mechanical vibration results. Because the frequencies of these vibrations are above the audible frequency domain, the vibrations produced are termed "ultrasound." Mulwert and Voss reported the first ultrasound therapy intervention in 1928 when they tried to cure certain deafness with ultrasound irradiation. Pohlmann, in 1939, made the first ultrasound therapy equipment for treating humans. In 1942, K. Tr. Dussik was the first to attempt to apply ultrasound for diagnostics. After World War II, ultrasound was used in different fields of medicine. The one-dimensional method (A-scan) was followed by the two-dimensional method (B-scan). Essentially, these are imaging methods with which place and form of tissues and organs can be examined.

By the application of the Doppler effect, ultrasound was expanded to dynamic measurement areas. Reflection of ultrasound from certain moving parts of the body makes the measurement of radial velocity of the reflecting surface possible. This phenomenon is applied, for instance, in measurement of the blood flow velocity and in the examination of fetal heart movements.

Considerably higher power must be applied in the case of therapy. Accordingly, the problem of regulating and making accurate measurements of ultrasound dose and energy had to be solved. Today, medical application of ultrasound is expanding rapidly, and equipment with new features appears on the market continually. As a result, quantity and diversity of knowledge required for the application of ultrasound is growing.

Microscope and Endoscope

Most likely, Zacharis Jansen, a Dutch optician, discovered the compound microscope in 1590. Its general use gave enormous impetus to the development of medical sciences. With its help, otherwise invisible elements of the body could be studied. Since this discovery, many varieties of microscopes have been developed. At the far end of the spectrum are sophisticated devices, such as the electron microscope and the atomic-force microscope.

For centuries, physicians wanted to directly visualize the inner parts of the functioning body. Various endoscopes were developed to assist in achieving this goal. The major improvement in endoscopes started with the invention of Bozzini, a physician in Frankfurt. Bozzini succeeded in introducing a beam of light into a hollow organ and directing the reflected light to the eye of the observer. The technician, Nitze, constructed the first truly practical endoscope. These instruments were used for rectoscopy and cystoscopy. From that time onward, the endoscopes have been continuously improved. Nowadays, endoscopes and laparoscopes furnished with flexible fiber optics or with cylindrically shaped lens systems (the Hopkins-optic) are in use. With the help of these modern devices, minimally invasive diagnostics and surgery progressed rapidly. The diagnosis and therapy of the digestive system, rectum, bladder, respiratory tract, joints, and abdominal cavity can be carried out with less trauma than with the conventional methods, which typically required large incisions. Introduction of catheters,

biopsy forceps, electrocoagulation instruments, and lasers can be done with devices evolved from endoscope.

Laboratory Devices

Together with the development of biology, medical science, and measurement techniques in chemistry and physics, the variety of laboratory devices has increased enormously. With the help of the modern laboratory automatons, the number of different measurements done today is on the order of hundreds of millions per day. Of course, this practice also raises the number of the companies that supply the reagents and disposables.

Surgical Instruments

These instruments are usually not of concern to clinical engineers. However, for the sake of completeness, they should be mentioned. The number of surgical instruments ranges in the thousands. Many of them are engineering marvels, the products of cutting-edge fabrication technologies and advances in metallurgy and materials science.

Patient Monitoring Devices for Intensive Therapy

Modern technology and engineering opened the door for the application of individual equipment in systems. Two good examples are the complex array of equipment in the operating theater or the installations in the intensive care units. Patient monitoring systems, respirators, defibrillators and others constitute an integrated system. The measurements of one device might affect the operating parameters of the other. The harmonized functioning of these devices has required the attentive presence and intervention of the physician or intensive therapy nurse.

One ongoing development is the automation of processes and the involvement of information technology. The patient will become a part of a feedback loop, in which the system automatically sets and maintains the optimum parameters. Such parameters might include pulse, respiration, ECG, blood pressure, and blood sugar level. This, to some extent, is the vision of the future; but considering the pace of development in the last few decades, one may safely say that this is not the illusion of the far future. The science of robotics is enabling machines to replace some of the operations of the surgeon. Will the human ever be completely replaced by machines?

Understanding the Physical World

In the previous paragraphs the development of medical device technology was introduced in a nutshell, through examples. These brief episodes demonstrate well that, in the course of development, combination and interaction of different scientific disciplines have played an important role. Formerly, usually one person facilitated this interaction. In the time of Hippocrates, for example, science-minded people had wide interest and philosophical inclination. Because of the lesser quantity of the available scientific knowledge at that time, surveying it was easier for one person. This helped to develop those statements and discoveries that demanded multidisciplinary knowledge from the inventor. Such was the situation up until the last few centuries.

Taking a great leap in historical terms to the Enlightenment, the progress in understanding the law's of nature was rapid and substantial. The seventeenth century is considered to have been the period of brightness and the mind. The Bernoulli brothers (Jacob and Johann), Herman von Helmholtz, Gottfried Wilhelm Leibnitz, and Isaac Newton towered above the geniuses. Newton, in his *Principia*, who also built upon the observations of Galileo, Copernicus, and their contemporaries, gave the best description of mechanics of their time. With the infinitesimal calculus, and with Newton's mechanics as a basis, Leonhard Euler, a Swiss mathematician, described the movement of solid bodies and developed the basic equations of hydrodynamics. Galvani and Volta laid the foundation for knowledge of contemporary electricity.

During the eighteenth century and beyond, the bulk of work went into observation and understanding natural phenomena, the qualitative recognition of the laws of nature, and their formulation in statements and equations. The growing amount of knowledge and the immersion into the details necessarily steered scientists toward specialization. The epoch of polymaths began to fade away. Due to the prompting effect of the industrial revolution, demand on practical application of sciences strengthened. A technical revolution followed the scientific revolution. Application of discoveries accelerated. The number of inventions grew. The steam engine and the principle of the dynamo, followed by the general use of electricity, had great effects on almost every aspect of life. Medical science provided its share, too. Physicians discovered the potential of electrical phenomena. For instance, they introduced electrical shock therapy for a variety of purposes. The rapid development of basic sciences, physics, chemistry, and biology, and the engineering sciences, together with the demands emerging from the medical side, gave impetus to the developers of medical devices. The pace of development during the nineteenth century became significant. Increasingly, humans began to understand the phenomena of their surroundings, the laws of nature, and their effects on the individual as well as on society. Discoveries and inventions followed each other.

During the first part of the twentieth century, significant milestones included the discovery of X-ray, the introduction of ECG, and the development of anesthetic and respiratory equipment. Then came World War II and the harnessing and release of atomic energy, with one of its practical applications being nuclear medicine. Discovery of special semiconductors and transistors in the 1950s also gave a large thrust to the development of electromedical equipment.

During the first half of the last century, pharmaceuticals dominated medical advances. But since the 1960s, developments in medical engineering have been

unprecedented. In the second half of the last century, a great variety and number of medical devices entered hospitals and consulting rooms. Today, the number of different medical devices is around 10,000. If one considers the variations of the equipment manufactured by different companies for the same application, then this number increases to tens of thousands.

It is no exaggeration to state that health care and health care organizations are among the most complex and complicated structures of our society. Physicians must select from an extensive arsenal of methods, materials, instruments, and from combinations of them, and they must do so with the intention of providing the best care for the patient. Evidently, in such a complex system, various specialists must work together. In the course of time, pharmacists appeared in the hospital, joining the physician and the nurse. They helped with the proper handling and preparation of the vast number of pharmaceuticals available. As with pharmaceuticals, the introduction of a multitude of increasingly complicated medical devices urgently emphasized the importance of the support of specialists in physics and engineering. By the 1930s, medical physicists began to appear in hospitals. Their tasks were to handle and control X-ray equipment, to perform dose measurements, and, later, to work with other ionizing radiation sources. Dose planning and control and quality assurance also became their tasks. Nowadays, they are often found working with non-ionizing radiation, such as ultrasound and lasers, as well.

Since the 1970s, complicated equipment such as patient monitoring systems and heart-lung machines have made indispensable the presence in hospitals of those specialists called clinical engineers. Soon it became evident that besides requiring technical knowledge, these clinical engineers needed experience in other fields. Apart from becoming knowledgeable about the human body, these engineers needed to know how to communicate with the medical staff and to have experience in hospital management and administration. Step by step, the concept of clinical engineer was developed. In our time, clinical engineering has become an accepted profession in many countries.

The number, variety, and complexity of medical devices, combined with the growth of informatics, made it important and possible to think and work with systems. Health informatics gradually gained ground all throughout health care. The great quantity of patient data can be organized and managed only with the help of informatics. Informatics finds particular importance and applicability in acquisition, processing, storage, archiving, retrieving, transmission, and display of diagnostic images.

The Future

The current trend will continue. The fields of medicine, engineering, and science will develop independently but will help each other, a phenomenon known in electronics as "bootstrapping." Progress in medical science makes new demands upon engineering, which in turn are reflected in the development of new methods and equipment. New engineering technologies provide fresh possibilities for physicians. Cellular and tissue engineering come closer to the routine application of their results. The introduction of nanotechnology will soon yield practical applications. Robotics will open up new opportunities in surgery. The combination of these technologies will result in spectacular achievements. As an example, new techniques in heart surgery combine robotics and endoscopy, thus enabling an operation without the need to fully open the thorax, without the need to use a heart-lung machine, and without having to lower the patient's temperature. The field of gene technology shows promise of progress and advancement.

Biomedical engineering was literally created and developed during the twentieth century. Considering the accelerated pace of development of the present, it is impossible to predict developments that will occur over the next few decades. However, it is possible to affirm with confidence that the physician-engineer relationship and the importance of clinical engineers in health care will remain and grow in prominence. Besides engineers who are directly involved in hospitals, clinical engineers will also play an important role in research and development. Equally important is the role of the engineers who are employed in medical equipment factories. In summary, relatively little is known about the forthcoming development in this century; however, even this modest foresight hints at enormous technical progress.

Social Effects

What are the impacts on the society of the rapid technical progress taken place this century? Colossal resources of energy are at the disposal of mankind. The bulk of physi-

cal work has been taken over by machines. Comfort of life has increased. Initially, humans saw only the pleasant side of this progress, that living conditions improved. Only in the last few decades has mankind started to feel and get to know in more detail the harmful effects of the environmental hazards that accompanied the technical revolution and which affect the entire biosphere.

In addition to environmental damages, the technical revolution has affected the practice of medicine, which now must face new maladies. As illnesses shift in their nature and significance, adaptation of health care services requires continuous change and development.

The extended life span of humans brings into focus health problems of the aged. Attending to the health problems of the aged will impact medical device development in two ways: (1) requirements for innovative medical devices for home use and (2) increased number and variety of devices for hospital use. Those in the aged population are not necessarily ill, in the general sense, but they require special support structures and medical devices which may significantly differ from those found in a general hospital.

In the long run, man-made technical means influence the trend of human biological evolution. The so called "homo technomanipulatus" is coming into being. Abilities, once so important, like physical fitness, the subtle function of the sensory organs—the anatomy that was so well matched to extensive movement are all gradually diminishing. In place of these, new abilities required for intellectual work are augmenting. In the longer-term, negative effects of these will be significant in health care. For instance, the incidence of the diseases of the locomotor, cardiovascular, psychic, and neural systems will increase. The results of a recent research project demonstrated the likelihood of manipulation of the human genome. As a consequence, deliberate or accidental modification of the human genes will be possible. The "homo genomaniplulatus" may come into being. Impact of this on humans is unimaginable today. The consequences of gene manipulation for our descendants' are difficult to foresee. We do not know the future of the biosphere. However, genetic manipulation of humans will soon become reality. But we do not know to what extent the new features created in this way will be advantageous or rather disadvantageous in the biosphere that is also changing beyond our control and in an unknown way. Because of the different and long time constants of the processes, one cannot survey the whole system (man + biosphere).

It is clear that health care must be vigilant and ready to respond to new challenges. While some of the impact of advances in technology may be deleterious, it is some comfort to know that predicting and reacting positively to this impact is within mankind's reach. It is imperative that those engaged in health related technical activities must continuously progress by advancing to appropriate knowledge levels and developing technological means so as to enable the generation of solutions to complex and rapidly mutating immersing problems. Taking all of this into consideration, the knowledge and efforts of clinical engineers will be appreciated in the future, as they are in the present.

Technology in Health Care

Jonathan A. Gaev
International Programs, ECRI
Plymouth Meeting, PA

Medical technology encompasses a wide range of medical devices. Practicing clinical engineers often focus on a few areas of medical device technology, such as defibrillators, electrosurgical units, and physiological monitors. This chapter addresses the entire spectrum of medical devices with which the clinical engineer should be concerned, the medical devices that are required for almost all diagnostic and therapeutic medical interventions. These devices have different lifetimes because they may be disposable, reusable, or implantable. They are made of a range of materials, such as plastics, ceramics, metals, wood, and biologic products, and they rely upon all types of physical principles for their functioning (e.g., electronic, hydraulic, mechanical, chemical, optical, and radiation). People use them to improve patient health. Medical devices, as distinguished from drugs, achieve their action without directly entering metabolic pathways.

Like the systems of the body, devices are specialized to perform specific tasks. Over 5000 different types of devices are on the market today, and the clinical engineer must be comfortable working with this great variety of devices. The main features to consider when working with a medical device in a health care setting are the clinical condition to be addressed, the user of the device, and the requirements for use, including power, training, storage, maintenance, and cost. Reusable devices, disposable devices, accessories, and consumables must be considered in the effective management of medical device technology. Devices are usually part of a chain of equipment. For example, an X-ray unit might require film and film processors in order to produce an image for a radiologist to read.

It is almost impossible to find a medical intervention that does not involve medical technology. Simple devices, such as a scale, stethoscope, thermometer, latex gloves, and sphygmomanometers, are part of almost all medical examinations. Complex devices include imaging equipment, clinical laboratory equipment, and implants. Some devices are used just once, and some are used for 20 years or more. The tremendous range of application, sophistication, cost, life span, and functionality of medical devices and their intimate relationship with people set them apart from many other technologies. Training, maintenance, selection, and use must be considered to ensure that the device will do its job of helping people to stay well. This chapter discusses the role of medical device technology in health care.

The Health Care Market

Epidemiology

The goal of the health care provider is to solve clinical problems (not to buy, use, or maintain medical devices). One must understand the relationship between the clinical problem and the devices used. For example, coagulation of blood can be achieved by using a bandage costing ten cents, an electrosurgical unit costing \$3000, or a laser costing \$120,000.

The causes of morbidity and mortality will vary. In wealthier populations and countries, people tend to live longer and tend to have more chronic diseases, including coronary artery disease, cancer, stroke, and chronic obstructive pulmonary disease. Poorer populations suffer more from infectious diseases, including diarrhea and malaria (Coe and Banta, 1992). The world's 10 leading killer diseases in 1996 (MHMG, 1998a) are listed below:

- Coronary heart disease: 7.2 million
- Cancer (all sites): 6.3 million
- Cerebrovascular disease: 4.6 million
- Acute lower respiratory infection: 3.9 million
- Tuberculosis: 3.0 million
- Chronic obstructive pulmonary disease: 2.9 million
- Diarrhea (including dysentery): 2.5 million
- Malaria: 2.1 million
- HIV/AIDS: 1.5 million
- Hepatitis B: 1.2 million

Health Care Spending and Health

Most of the world delivers the majority of health services through the public sector. The United States is an exception, delivering almost all services through the private sector. In

1998, in the developed world, over \$2,000 was spent per person each year, representing on average, 8% of a nation's GDP.

For comparison, Table 80-1 shows a sample of countries with the highest per capita expenditures in their respective regions of the world. Although the United States spends more on health care than any other country in the world, its population does not enjoy the longest lifespan. Therefore, one must ask, "What does money buy in terms of health?"

In wealthier countries, demand for drugs and devices is strong. Long-term care for the aged represents a large and growing expenditure. In less-wealthy countries, spending is focused on drugs, which generally are quite cost-effective to treat diseases. Less funding is available for medical devices and for device maintenance (Table 80-2). In many developing countries, the majority of medical devices do no function, because of lack of maintenance, training, disposables, power, or other requirements.

Devices represent only 4.4% of the total spent on health care. Because of the size of the market, this money is spent differently in each part of the world. In the larger markets of the developed world, purchasers have direct relationships with device manufacturers. In the smaller markets of the developing world, manufacturers work through local distributors. Information such as hazard warnings and recalls can be lost because of these intermediaries, and spare parts and repairs tend to take much longer when working through distributors.

Devices are a relatively small part of worldwide health expenditures (Table 80-3). Much more is spent on drugs than is spent on medical devices. About one-half of the drug expenditures are for treatment of cardiovascular, respiratory, and central nervous system problems and infectious diseases.

Medical Device Sales

In the United States, imaging equipment and other "big ticket" items represent a smaller portion of the medical device market than do disposable devices (Table 80-4). In 1996, of the medical devices sold, X-ray equipment comprised 7%; general electromedical equipment, 14%; for surgical appliances and supplies, 30%; surgical and medical instruments,

Table 80-1 Health Care Expenditures and Life Expectancy

Area	Health care	Health care	Life expectancy	Life expectancy
	spending % GDP	spending Per Capita	male Born 1999	female Born 1999
	\$USA	\$USA	Years	Years
United States	14	\$4,270	73.8	79.7

Argentina	8.2	\$676	70.6	77.8
South Africa	7.1	\$268	47.3	49.7

From WHO Report 1997 estimates, Table 8 pp 192-195; Table 2 pp 156-163.

Table 80-2 Estimated health care expenditures in 1996

	Developed world	Developing world
Total (\$ billion)	\$2,374	\$552
Hospital care	37%	42%
Physician services	19%	22%
Drugs and medical	12%	19%
Nondurables		
Long-term care	6%	3%
Other	26%	14%

From Medical Health care and Marketplace Guide (MHMG, 1998b)

Table 80-3 Medical Device Expenditures 1996

Worldwide (\$ billions)	\$129
United States	42%
European Union	27%
Japan	15%
Rest of the world	16%

From MHMG, 1998c.

Table 80-4 Medical Device Sales 1999

Product	1999 Revenue \$million
Incontinence supplies	\$2010
Home blood glucose monitoring products	\$1710
Wound-closure products	\$1500
Implantable defibrillators	\$1334
Soft contact lenses	\$1159
X-ray equipment	\$1140
Orthopedic fixation devices	\$1122
Pacemakers	\$1112
Examination gloves	\$1088
Coronary stents	\$1086
Ultrasound equipment	\$1070
Arthroscopic accessory instruments	\$919
Magnetic resonance	\$890
Computed tomography	\$790

From MDDI, 2000; MHMG, 2000.

30%; diagnostic products (mostly in the clinical laboratory), 15%; and dental equipment and supplies, 4%.

Clearly, most of the money spent on medical devices does not go toward "big ticket" items. In hospitals, labor is the largest expense, averaging 53.8% in 1998 in the United States (Health Forum, 2000). Capital medical equipment is a small part of the budget of a typical hospital. Disposables are also a significant expense for most hospitals and may exceed the cost of capital medical equipment (Table 80-4).

One sees a similar pattern when analyzing individual procedures. For example, in one institution's costs for a thoracotomy for lung cancer, salaries accounted for 54%, supplies and medication 27%, and capital equipment only about 7% (Marrin et al., 1997).

Definitions

Although medical devices do not represent society's largest health care expense, they remain crucial to the delivery of health care. In all societies, government often is involved in use and sale. The United States Food and Drug Association defines a medical device as: "an instrument, apparatus, implement, machine, contrivance, implant in vitro reagent, or similar or related article, including any component part, or accessory, which is:

1. Recognized in the official National Formulary, or in the United States Pharmacopoeia, or any supplement to them;
2. Intended for use in the diagnosis of disease or other conditions, or the cure, mitigation, treatment, or prevention of disease, in man or other animals; or
3. Intended to affect the structure or any function of man or other animals, and which does not achieve its primary intended purpose through chemical action within or on the body of man or other animals and which is not dependent upon being metabolized for the achievement of any of its intended principle purposes." (MDA, 1976)

Devices that meet this definition include disposables (some are reused for a single patient, and some are thrown away after a single use), reusables, and implants. Medical devices are part of the elements of health care that include medical procedures, surgical procedures, and drugs.

The medical device technology area of medical information-based devices, including information systems, diagnostic tools, picture archiving and retrieval systems (PACS), and electronic patient records is new. The trend certainly is to include more information-processing capability in all medical devices (see Chapters 97, 98, 100, and 102).

Attitudes

The intimate relationships among the technology, the practitioner, and the patient are critical distinctions in the medical field. Devices are used to affect the health of the patient. The practitioner feels responsible for achieving the best possible result, so he must feel comfortable using the devices. Practitioners need to have experience using the devices and must believe that the devices work properly. Familiarity with devices and the results that can be obtained with them are important to the health care professional. Clinical effectiveness is hard to prove, and practitioners can be skeptical about acceptable results being obtainable via a new technology. This need for reliability and consistency and the need for training in the use of technology lead many medical professionals to resist changes in technology unless a clear benefit can be demonstrated in clinical practice. If the current device is adequate for a practitioner's art, the practitioner will resist acceptance of new technology, especially if it will require more training, or if it will change the way the clinician works.

For the clinical engineer to perform effectively, the attitudes and the environment of the user must be understanding. Health care professionals are trained in the use of devices, but not necessarily in the general principles of engineering, mathematics, or physics relating to the devices. Many health care professionals see devices as tools; they prefer not to spend too much time on the tool, so that they can focus on the clinical needs of their patients. Time is usually at a premium in health care settings, so the health care professional does not always have the necessary amount of time to learn how to use a new device. Clinicians might be unaware of alternatives to the devices they are using. Clinical engineers can bridge the gap between technical knowledge and clinical needs and thus can help the clinician to deliver the best possible patient care.

Nomenclature and Codification

Nomenclature systems are essential to managing the great variety of medical devices. A unique reference for each device enables one to organize information related to that device, such as work orders, service history, service contract information, hazards, recalls, in-service training, and other device-related expenditures. The problem is similar to that facing a library. Having millions of books is a useless resource if they cannot be located. Just as a library uses a classification system to organize its books, the clinical engineer needs to have a nomenclature system to uniquely identify medical devices. Maintaining the nomenclature system is quite time-consuming, so most institutions use a standard system, such as the Universal Medical Device Nomenclature System™ (UMDNS™), which is available without charge from ECRI (www.ecri.org).

It is no surprise that there are standards, rules, and regulations for the use of technologies that impact health. In ECRI's directory of national and international standards, there are over 43,000 medical equipment standards, prepared by over 1400 agencies throughout the world. Clinical societies also publish guidelines for their members regarding medical technology. The National Guidelines Clearinghouse (<http://www.guideline.gov>) is a good source. Some hospitals require the practitioner to complete a training program before using certain technologies, such as surgical lasers or endoscopes.

Safety

Safety is also related to standards, guidelines, and, mostly, common sense. Maintenance and device selection are important, but the majority of the problems come from the way the equipment is used and the relationships between the device and other systems (see Chapter 60). Energy-producing devices, such as lasers and radiological equipment, have special engineering-safety requirements.

Device classification systems depend on perspective. If one were classifying devices for safety, one might use high risk for life support devices; medium risk for devices whose failure would affect patients, but not cause serious harm; and low risk for devices whose failure would not be likely to harm patients.

The Environment of a Device

Devices do not help people all by themselves. They help only when they are part of a medical intervention. An intervention requires a patient, a practitioner, and it might require a drug, device, and medical facility. One must understand this context to ensure that devices contribute appropriately to clinical outcomes. More specifically, one must take a systems approach (see Chapter 59) and must consider the four following interfaces (Figure 80-1) (see Bruley, 1994):

- Device-user
- Device-patient
- Device-environment/facility (hospital, home, or other)
- Device-accessories/disposables/consumables

Device-User

Although one thinks of the doctor as the user of the device, most of the time a nurse or technician is the actual user. One must be aware of the differences in perspective, training, and education between the person who specifies the device and the person who uses it. Users must be trained to operate the device and to interpret the results. Most of the medical device problems in the hospital are related to user error. Frequently, the clinical engineering department can help to reduce errors by training users (see Chapter 74).

Device-Patient

Almost all devices touch patients or draw samples from the patients' bodies. The wide variation in the patient population must be understood for an adequate understanding of ways in which the device will accommodate that variation. It is crucial to understand exactly how a device interfaces with a patient and how it can accommodate a range of patients. Certain groups of patients, such as newborns, children, very large or small adults, and elderly patients, might have special needs. Some devices require special accessories so that they can accommodate groups of patients.

Device-Facility

All devices have conditions and requirements for their storage and use, including temperature, humidity, electrical power, water, pH, shielding from electromagnetic fields, and connection to specialized gases. Be especially careful when devices are designed to be used in one environment, such as a major hospital, but are used in another environment, such as a home (Dyro, 1998). Similarly, caution must be taken when devices designed for adults are used with children. Even simple devices, such as sharps containers, have contextual implications. In a children's hospital, they must be out of the reach of the child because the child might consider the device to be a toy and thus might want to put his hand inside to play with it.

Device Interfaces

Figure 80-1 Device interfaces.

Accessories, Disposables, and Drugs

Device-Accessories/Disposables/Consumables

Most devices have reusable and disposable components. An infusion pump has a disposable infusion set; a defibrillator may have disposable electrodes; and an X-ray unit typically has a film cartridge. The entire group has to function correctly. The manufacturer of the device might not produce or sell the disposables or consumables. Conversely, the manufacturer of the disposable or consumable might not sell or produce the medical device. Sometimes, only one manufacturer makes the disposable or consumable. The relationship between the disposables and the consumables affects the use and cost of the device. The profit from consumables is so high for some clinical lab equipment that the manufacturer will offer the device for free if the hospital commits to purchasing the consumables from the manufacturer.

Disposable Devices

Disposable devices are designed to be discarded after one use, or after multiple uses on the same patient. Some of these devices are quite expensive (catheters used in catheterizations can cost \$400 or more), so there are powerful financial incentives to reuse devices, even though the devices were designed for a single use. Some institutions reuse single-use devices. There is a great controversy about the risks to the patient when single-use devices are reused. In many cases, there are alternatives to a reusable and disposable device.

Some associate the following characteristics with reusable devices: Strength, difficulty to clean, and low cost (i.e., if labor costs to reprocess the device are low). Disposable devices are thought to be cleaner, easier to keep sterile, less robust, and, ultimately, more expensive. When making a choice, it is important that one be certain as to the reason for deciding on a reusable or disposable device, and to review assumptions as time goes on. The cost of reprocessing can change as labor costs change and as new technologies to help in reprocessing and sterilization become available. Both types of devices, reusable and disposable, still need to be inspected before use.

Differences Between Devices and Drugs

Drugs and devices sometimes come together directly, as in an intravenous (IV) pump, and indirectly, as in the case of clinical lab analyzers, often determine what drugs are prescribed by the clinician. Devices such as stents are now impregnated with drugs during manufacture. The line between drug and device is changing, so it is important to appreciate the differences between them.

Devices and drugs are used to help patients, require a trained person. Drugs, however, do not require periodic maintenance, do not break, and do not require as many people to keep them working. Drugs do not have a "work history," nor do they require service contracts and the same type of record keeping. Teaching a doctor how to prescribe a drug is quite different from teaching a doctor, nurse, or technician how to use a medical device.

Example: Treating Patients with Diabetes

The following discussion details the requirements for treating diabetes, one of the world's most common diseases. Diabetes is expected to affect over 200 million people worldwide by 2005. In the United States, about 10 million people have been diagnosed, and another seven million have the disease and do not know it. Annually, over 600,000

new cases are diagnosed in the United States, where the disease afflicts men and women in equal proportion. Diabetes is the seventh leading cause of death in the United States (NDIC, 2001).

Diabetes and its associated complications are among the most prevalent, costly diseases in the world. The worldwide market for glucose-monitoring products exceeds \$4.7 billion. In the United States, direct costs of diabetes care are estimated at about \$50 billion, almost 6% of the total personal health care expenditures, while the complications of uncontrolled diabetes result in nearly \$100 billion in annual medical costs.

Diabetes is a chronic disorder of blood glucose regulation that commonly results in the development of cardiovascular, ophthalmic, neuropathic, and nephropathic complications. It is classified by two major types: Type 1 (lack of insulin production and release) and type 2 (resistance to insulin's actions). In type 1 diabetes, islet cells have been destroyed by an autoimmune response, and insulin production is reduced to insufficient levels for maintenance of blood glucose regulation; thus, insulin deficiency is the main cause. In type 2 diabetes, the body cannot properly respond to the insulin produced by the pancreas. Glucose remains in the blood instead of supplying the body with the fuel it needs.

In the United States, about 500,000 people have type 1 diabetes, which typically begins in childhood. The rest have type 2 diabetes, which usually develops after age 40. Type 2 diabetes is often found in elderly people and is also associated with obesity. Several recent studies have shown that keeping glucose levels close to normal was associated with a major reduction in the secondary long-term complications of diabetes. For a patient with type 1 diabetes, this management requires blood glucose testing several times per day, three to four daily insulin shots, and lifestyle changes. Tight control is recommended as an important way to delay the onset and to dramatically slow the progression of long-term complications from diabetes, such as retinopathy, neuropathy, nephropathy, and cardiovascular disease. About 40% of the patients who are diagnosed with type 2 diabetes will require insulin therapy and will benefit from tight control of their blood glucose levels. The disease must be managed during the life of the patient because there is no cure.

The diagnosis and treatment of an adult patient with type 2 diabetes is discussed below. The equipment used, the location of the equipment used, and the practitioners involved in treating the patient are described. The equipment ranges from simple to complex devices and includes disposables, reusables, and home care equipment (i.e., a wide range of technology involved in treating a patient). The relevant equipment, assuming that the disease progresses significantly, is described. Fortunately, not all patients will suffer all symptoms of the disease.

Diagnosis

During a routine physical examination, the patient might report symptoms such as excessive eating, thirst, frequent urination, or weight loss. Blood tests confirm the diagnosis. Because many patients have no symptoms, screening is performed by measuring the glucose level as part of general blood tests performed on patients over age 45. Urine tests for glucose are no longer used to diagnose diabetes in the United States.

Blood is drawn in a physician's office and is contained in either a sealed test tube that has a preservative to inhibit glycolysis, or in a special tube with a barrier to keep the serum/plasma separate from the red blood cells. To prepare the sample so that it can be read on the clinical chemistry analyzer, it must be spun on a tabletop centrifuge (acquisition cost: \$2000) at 3200 to 3,500 rpm to separate the serum/plasma from the rest of the sample. (Most clinical laboratory equipment does not accept whole blood—only serum/plasma). The sample should be stored cold and should be sent to the clinical laboratory within a few hours of being drawn.

Once received by the clinical laboratory, the blood sample is tested on a clinical chemistry analyzer (acquisition cost: \$100,000) by a laboratory technician. Glucose levels outside of predetermined values indicate that the patient has diabetes. The tests should be repeated on another day, to confirm the diagnosis.

Diet and Exercise

Many patients with type 2 diabetes can be treated with diet and exercise. Counseling is important. Ideally, the patient meets with a dietician or a nurse educator to obtain advice regarding changes in diet and activity. The patient's weight is monitored at home and during office visits, using a patient scale.

If diet and exercise do not control the levels of blood glucose, the patient will be prescribed oral medications, or, in some cases, insulin. He or she will need to monitor blood glucose levels at home, using a blood glucose monitor.

Blood Glucose Monitors

Blood glucose monitors are portable, battery-powered devices (ECRI, 2000a). The patient places a drop of blood from the finger onto a paper test strip, which is impregnated with a glucose-specific enzyme that reacts with the glucose in the blood. The strip is inserted into the blood glucose meter and is read using either reflectance photometry or electrochemical technology to determine the glucose level in the blood. These monitors are also used to monitor blood glucose levels in clinical settings.

The average cost for home blood glucose monitors cost is \$55. They last about three years. (Hospital units, which have additional capabilities to store and transfer information, cost about \$,000) The strips cost about \$0.35 apiece, for home use (\$0.70 for hospital use). Assuming two readings per day, the test strips cost about \$260 per year. The worldwide market for glucose meters and strips is about \$3 billion dollars per year and is expected to double by 2008.

Persons with diabetes need to have their blood glucose levels measured by a clinical laboratory two to four times per year, depending on the severity of their disease. A hemoglobin A1c test is performed in the clinical laboratory using manual or automated equipment at least twice per year. Other tests, including kidney-function and urine-microalbumin tests, can be performed as needed.

Patients can be prescribed medications to help the body to use the insulin that it produces more efficiently. Most of these patients monitor their blood sugar at home by using a blood glucose monitor.

Insulin Injections

Some type 2 diabetes patients will require insulin injections in order to maintain appropriate blood glucose levels and thus to decrease their risk of complications, which can include blindness, kidney damage, nerve damage, and circulatory problems. Home monitoring using a blood glucose monitor is a critical part of the treatment.

These patients must inject themselves two or more times per day with insulin, using an insulin syringe. Insulin must be stored in a refrigerator and must be protected at all times from temperatures greater than 86° F (30° C) or less than 36° F (2° C). Injections are given at room temperature to facilitate absorption, so the patient may keep a personal supply at room temperature. Insulin is stable for one month at room temperature. The patient always needs to have an extra vial of insulin on hand in case of emergency.

The syringes cost about \$28 per box of 100. They are sold as single-use devices, although some patients choose to reuse them. The annual cost for two syringes per day is about \$200 per year.

Blood Testing

Patients with Type 2 diabetes normally will have a blood glucose test performed every three months, and a hemoglobin A1c test performed every six months. Glucose monitoring represents 19% of all *in vitro* diagnostic tests performed annually in the United States.

Because the patient uses a blood glucose monitor at home to check their glucose levels and to adjust their insulin dosage, it is important to compare the results using home machines to those obtained by the clinical chemistry analyzer. Agreement should be within 15%.

Because diabetics are at greater risk of heart disease, cholesterol testing (or, more precisely, testing for lipids and triglycerides) is performed one or more times per year. Some diabetics will develop kidney disease, which may progress to the point where they require dialysis.

Dialysis

Dialysis is the removal of toxins from blood by a machine (ECRI, 2000b). Some patients can treat themselves at home by flushing their abdominal cavity (peritoneal dialysis—typically performed daily). More often, hemodialysis is required. It takes place during three sessions of five hours, using a dialysis machine in a hospital, nursing home, or other facility. The equipment required includes a water-purification system, dialysis machine (acquisition cost: \$25,000), dialyzer, and disposables. The patient is connected to the machine by a dialysis technician. The machine filters the patient's blood, toxins are removed, and the blood is returned to the patient. A medical specialist supervises the operation of the facility.

Eye Examination

To prevent blindness, an ophthalmologist performs detailed eye exams several times per year. Retinal surgery is often required and is performed using an ophthalmic laser (ECRI, 2000c) (acquisition cost: About \$55,000).

Heart

Because diabetes can lead to coronary artery disease, the cardiovascular condition of the patients is carefully monitored using EKG and stress tests. Prevention includes control of weight, exercise level, and diet. If coronary artery disease develops, bypass surgery, stents, angioplasty, and laser treatments may be performed.

Circulatory complications can lead to the need for amputation of the feet and legs. More than half of the amputations that take place in the United States are performed on diabetics. Wounds do not heal well for diabetics, and wound-healing on extremities is difficult.

Summary of Devices used in Diabetes

Diabetes is one of the most costly diseases in the world. The direct cost of diabetes in the U.S. represents about 6% of the total personal health care expenditures. Treating the complications of this terrible disease costs nearly \$100 billion each year.

The devices that are used to manage diabetes are found in home, doctor's offices, hospitals, and specialized centers. Patients, caregivers, doctors, nurses, laboratory technicians, and medical specialists use the equipment. The equipment chain includes syringes (\$0.28) scales, sphygmomanometers, stethoscopes, fundoscopes, blood glucose monitors, refrigerators, and clinical chemistry analyzers (\$100,000). The annual cost for syringes and test strips for home glucose measurements is \$460. More sophisticated equipment is required when complications occur. All of the equipment in this chain is required in order for the patient to receive proper treatment.

Jay W. Hall

Manager, Clinical Engineering, St. John Health
Detroit, MI

Pam Shuck-Holmes

Product Development Engineer
Detroit, MI

Clinical engineers in the hospital setting use modern technical, scientific, engineering, and management training. Specialization, knowledge, and experience of clinical engineers serve humankind by contributing significantly to the provision of safe and effective medical technology. This view is in harmony with the American College of Clinical Engineering (ACCE) definition of a clinical engineer as “a professional who supports and advances patient care by applying engineering and managerial skills to health care technology” (Bauld, 1991). In this chapter, the authors, reflecting on over 40 years of collective experience as clinical engineers in a hospital setting, describe their role in designing, manufacturing, evaluating, and controlling medical devices to ensure their safe and effective application in health care.

The extent to which a clinical engineer (CE) is able to perform a responsible function in the hospital setting depends to a large degree on the acceptance and understanding of their roles and capabilities by the hospital administration and staff. Without the full support of the hospital, from the lowest to the highest levels, clinical engineers cannot function to the best of their abilities. Thus, when empowered, clinical engineers not only follow a course of action specified in good clinical engineering practice guidelines but also go beyond the call of duty. The CE’s clients (i.e., doctors, nurses, respiratory therapists, imaging specialists, other hospital staff, patients and their families, health maintenance organizations [HMOs], and preferred provider organizations [PPOs]), are usually well informed about medical technologies, which is a result in part, of the Internet and the accessibility of up-to-date information that once lay only in the books and journals stored in the deep recesses of libraries.

As clinical engineers, the authors have striven, consciously and subconsciously, to change the staff’s perception of clinical engineers as simply repairmen armed with a cell phone and three pagers dangling from their belts. At William Beaumont Hospital, CEs have focused on a systems approach to medical technology management. For example, hospital beds are not treated as simply a support surface for patients. The CE considers a hospital bed from the perspective of mechanical design, safety features, operating mechanisms, interfaces with the patient, intelligent nurse-call and alarm systems, and electrical power requirements. The CE analyzes the risks that the bed or its accessories pose to a patient, a nurse, or other equipment. Similarly, a robotic system includes the control device, all of the system components, the maintainers, the users, the storage environment, the physical-facility requirements, the specialized test equipment, and the training requirements. If all devices and systems were so perfect as to be predictable with no possibility of causing injury to the patient and user, then the need for clinical engineers would diminish. As this is not the case, the clinical engineer must identify and utilize available resources, examples of which include the purchasing department, which can provide financial analyses and assess the manufacturers’ financial health, test equipment, education and training in the scientific and engineering method, the manufacturers’ engineers and technical staff, the Internet, and device-user experiences.

As in the health care industry at large, in the hospital there are reactive and proactive elements in managing medical technology. The proactive, or preventive, component in medicine staves off the possibilities that can cause disease in a patient; e.g., preventing obesity can prevent the various diseases known to be associated with it such as diabetes (see Chapter 80). The reactive, or treatment, component addresses the patient who is already afflicted with a disease and the means for making them well again. This similar approach works well with the hospital’s overall goal of providing world-class customer service.

By describing clinical engineering experiences in this chapter, the authors provide practicing and prospective clinical engineers with a window into the clinical environment, showing ways in which CEs can help the hospital and patients and can advance health care. Engineers are never satisfied with the status quo. They constantly explore various solutions to a problem, seeking the optimal outcome.

The following anecdote captures the sense of the engineer’s fervent desire to seek engineering solutions to a problem. A long time ago, three folks were about to lose their heads on the guillotine. The first to go, a peasant, was asked by the executioner whether he wanted to have his head cut off while facing the sky, or downwards. He chose to look downwards. The blade was released but stopped just short of his head. Everyone took it as a miracle, and the peasant, to his extreme joy, was pardoned of his crime and was set free. The same thing happened to the second person, a lawyer, who chose to face the sky. The last person, an engineer, also choosing to face the sky, saw a knot in the rope and, just before the guillotine was released, cried out, “Hold everything—I see the problem!”

Design and Modification of Medical Devices in the Hospital

Clinical engineers thrive on change. They must, because medical technology is constantly evolving and changing. What seems to work well today could be superseded by something better tomorrow. Keeping up with the technology, and managing current and future needs are two services that clinical engineers can provide adequately. This goes well with the hospital’s goals of customer satisfaction by providing a holistic approach to medical care in a timely and effective manner. By helping to ensure an environment of safe and effective medical devices through good technology management, CEs enable clinicians to have the armamentarium that is needed to treat patients effectively.

Managing medical technology requires that both the medical device and the human factor component be understood. Ensuring that a medical device is safe and effective requires consideration of a host of factors, such as device design, construction materials, performance history in the clinical setting, the time in the market, FDA allowances and approvals, the manufacturer’s reputation, parts availability, and the vendor’s responsiveness to its clients’ needs. The human factor component of technology management looks at the human interface, which includes the patient, the clinician, the clinical/biomedical engineer, the service provider(s), and the manufacturer’s representatives. The hospital relies on the clinical engineer to facilitate communication among medical, nonmedical, and technical people. In addition to a working knowledge of the engineering process and specifications, the CE must be able to translate this information to such diverse professionals as doctors, nurses, financial managers, administrators, and technicians. At the same time, the CE needs to be able to transmit the clients’ feedback on a medical product to the manufacturer in a constructive fashion in order to resolve product problems in a timely fashion. Such feedback often results in product improvements as well.

Ensuring Medical Device Safety by Clinical Engineering

Various tools are available to the CE in the hospital setting to ensure the safety of medical devices. These tools, tried and tested by the authors, are listed below.

Equipment Selection and Evaluations

Clinical engineers conduct short equipment evaluations in-house to provide an educated estimation of the product’s usefulness, safety, and effectiveness (see Chapter 33). The

focus at this stage is on the product's suitability as a hospital standard. Such factors that must be considered include the manufacturer's financial health, which could determine whether the company will even exist in 10 years to support its products, and the product's record of performance.

The manufacturer's financial health can be assessed by analyzing information gleaned from annual reports, the Internet, and information services such as ECRI and the MDE Group. Purchasing and finance departments, by the nature of work that they do, are excellent resources. A product or a technology's track record, i.e., performance history, can be assessed through various sources, like interviewing user hospitals (vendors should be able to provide you with a list of hospitals and specific departments using their products), researching websites such as the FDA's Manufacturers And User Device Experience (MAUDE) database at www.fda.gov/, and ECRI at www.ecri.org.

Hospital technology management requires the monitoring of the life cycles of medical devices and systems (see Chapter 82). Systems comprise not merely the device, but also the support group of equipment and services that ensure its proper functioning and the competency of the user group. As a device approaches the end of its rated life expectancy, or if it has required inordinately high maintenance, this information must be conveyed to the user group. However, as experience shows, through constant communication, the clients (i.e., the hands-on staff members (users)) inform the CE of changes in a device such as deterioration, inaccurate measurement, or intermittent operation. When equipment has been identified for obsolescence in at least two years, work begins on selecting replacements.

At times, if the technology has not changed significantly, and the hospital is satisfied with the equipment, only a financial analysis of the pricing and service quotations from several vendors and manufacturers is required. Rapid changes in medical technology, however, dictate that even the most mature, most often used, and most accepted technologies, despite small generational improvements, should be compared with newer competing products and technologies through evaluation and, where necessary, clinical trials. Purchases that exceed a certain monetary value require a formal bid process entailing a request for proposal (RFP). The RFP is addressed later in this chapter.

A medical device becomes a hospital standard after the process of engineering evaluation, clinical trials, financial analysis (based in large part on the responses to the RFP), and selection as the most cost-effective product.

Clinical Trials

Participation in clinical trials is often an enjoyable, rewarding, and challenging aspect of the CE's work. The rapid growth in the biomedical engineering and its application to medical device technology market results in new and varied devices coming to market (see Chapter 80). This, in turn, presents the CE with more devices to evaluate, and more clinical trials to manage. Clinical trials find CEs becoming increasingly involved with the clinical and medical staff. The following is a list of many of the steps taken by CEs in managing and running a clinical trial:

- Obtain user department cooperation. (This tends not to be a problem because the department usually has requested the trial.)
- Arrange with the vendors and manufacturers for use of their products on a clinical trial of a duration of a few days to several weeks. Vendors are generally quite helpful, even supplying necessary, and often costly, disposables. Occasionally, the hospital supplies the disposables, especially if these are stocked items.
- Arrange with the vendors and manufacturers for in-service training of the staff involved with the trial. Obtain user and service manuals and make them readily available to staff. Schedule the trial so that most staff members have an opportunity to use and evaluate the product.
- Prepare a survey instrument that lists the desired specifications and evaluation criteria (e.g., ease of use). It is recommended that the survey instrument be on only one page, that the scoring be succinctly explained, that all terms used be understandable by the evaluators, that it states where to return completed forms, and that it contain a space for the name and mailing address of the evaluator.
- Clearly explain and document test methodology to ensure scientific validity of the study.
- Facilitate the monitoring of the devices for proper operation. This monitoring is usually the responsibility of the vendor or manufacturer. Because the vendor cannot be at the hospital at all times, a person in the department who is properly in-serviced should be designated as the resource person.
- Prepare a schedule lasting over a reasonable time that covers every possible step needed for the clinical trial. This is essential to ensure timely completion of the trial.

Negotiating for Safety Features

Sometimes certain features that help to improve the safety of the device are incorporated or are even sold as options. One should ascertain that the products provided for the trial have all the desired specifications and that the competing brands have the same features.

Note the willingness of the manufacturer to provide training of in-house maintainers to the same level as that of the manufacturer's field-service technicians. While in most cases, the manufacturer is quite willing to provide this level of training, the manufacturer occasionally claims that the proprietary nature of its technology militates against this. In these cases, one should relinquish servicing responsibility to the manufacturer or should negotiate a plan for utilizing in-house maintainers. The reasons for this are threefold: (1) immediate response to any equipment problems; (2) control over the safety, turnaround times, and costs; and (3) an immediate familiarity with the equipment and user group.

Education

In-Servicing of Clinical Users

The hospital should demand in-servicing for all new devices, including new standard devices that are upgrades of the old standard being replaced. Every department has an

assigned education specialist, who will need to be trained well so that that specialist can train other staff members, i.e., a train-the-trainer program. (Preferably, every user should obtain hands-on training initially.) That department should provide periodic in-servicing to users, either on demand or on a scheduled basis. Training should entail the theory of operation. A knowledgeable user is a prerequisite for efficient and safe use of medical devices.

The operation of complex devices is not easily mastered by typical users. It is, therefore, imperative that staff members continuously receive in-servicing that includes theory of operation, device features, and available resources with the goal of achieving staff familiarity with, and respect for, devices.

Training the Maintainers

Training and in-servicing should be provided to the servicing department. In particular, the in-house department should designate an education specialist, who will be the department's resource when questions arise.

Surveillance

Monitoring Medical Device Reports for Indicators

Researching the products' safety record can be done from several sources, including the hospital's medical equipment database; other hospitals; professional colleagues at local, regional or national conferences; the FDA; and ECRI. Maintaining a healthy communication line with every departmental client in-house helps tremendously because bits and pieces of information gleaned from users can prove invaluable in fine-tuning requirements to help keep the device in constant and safe operational condition.

Variance Reporting Process

Once the device has been purchased, has passed all safety inspections, and has been deployed in the hospital, surveillance of device performance and safety must occur. Any variance in device operation must be documented by means of a variance, incident, or adverse-occurrence report. (The title of such a report varies from institution to institution.) Any equipment that malfunctions or fails while in use on a patient must be investigated, and the variance, findings, and resolution must be recorded. The hospital has legal responsibilities under the Safe Medical Devices Act of 1990 (Alder, 1993; JCAHO, 1993; 21 CFR, 1995).

Cradle-to-Grave Management

This is a circular process of ensuring the continuity of making available at all times the necessary patient care equipment. Key to this process is the collaborative interaction among the client clinical staff, equipment maintainers, clinical engineers, and purchasing and financial analysis departments. Having responsibility for certain steps in this process and interacting with members of the project team, the clinical engineer stands to achieve a relatively safe, reliable, and cost-effective medical equipment inventory. The various components in this process include the following:

- Identifying the equipment to be purchased based on (1) clinical need (newer technologies have a way of rendering some older technologies obsolete);
- Planned obsolescence (the device is nearing the end of its rated useful life);
- Maintenance cost (the cost of maintaining a device exceeds depreciated value).
- Conducting pre-purchase evaluation of equipment. This process consists of two components: (1) performing engineering evaluations of competing products, and (2) conducting clinical trials, after narrowing the field down to a few candidates, to rank and select the best fit. Where the cost of purchase exceeds a certain amount, a more formalized pre-purchase evaluation is conducted, the RFP that involves the competing vendors and manufacturers to submit competitive bids that include the desired hospital specifications.
- Justification of the selected product and vendor and manufacturer is based on results of the pre-purchase evaluation or the RFP, cost-benefit analysis, life cycle costing, and the anticipated cost of ownership that includes, among others, expected cost of maintenance, depreciation, and obsolescence.

Clinical engineers, bridging the communication gap between clinicians and design engineers, can positively influence product design. Frequently, the CE explains to the manufacturer those things that can improve a product's efficiency and safety. Consider an example that the authors encountered in which foot supports used on an operating room (OR) bed repeatedly loosened and fell, but only on one side. Clinical engineering analysis revealed that the clamps' unidirectional thread enabled them to tighten down on the bed rail when a load (the foot) was placed on it but to loosen on the other side because the load applied a loosening force. Working with the manufacturer produced a clamp that works on either the right or the left side of an OR bed, without loosening.

At some time in the life of a medical device, it is likely that failure will occur. If the clinical engineering department provides in-house service, the CEs and BMETs must be trained at the same level as that of the manufacturer's service providers. Based on the manufacturer's recommended preventive maintenance schedules, the equipment is included in the scheduled maintenance program.

Maintaining an up-to-date database is a prerequisite to being able to predict early on a device's maintenance schedule. Also, including the projected useful life span of every device in this database enables the clinical engineer to begin the replacement process before frequent breakdowns occur, which would force the hospital to take costly measures like renting similar equipment to make up for the shortage.

Ensuring Efficacy and Effectiveness

Specifying Medical Devices for Cost-Effectiveness

Cost-effectiveness means that the product meets all of the desired specifications at a price that is competitive with, or even lower than, that of other vendors. Clinical engineers must work closely with the client to prioritize specifications, listing them as (1) those that are necessary; (2) those that are desired but that the organization can live without; and (3) those that are not needed, based on current and anticipated use. It is also best to work closely with the manufacturers, who can recommend the best devices to suit the hospital's needs without including unwanted or nonessential features that would drive up the price.

Anticipating Future Needs During Selection

Health care is a constantly evolving process, and, at times, it is even revolutionary. The instrumentation that is required to deliver current state-of-the-art technologies could become obsolete in a short time. For example, robotics is making great strides in the hospital setting. William Beaumont Hospital's medical laboratories are major users of robotic systems to perform various tests efficiently and cost-effectively, utilizing small specimens. It allowed the hospital laboratory to expand its capacity and capabilities without increasing skilled and educated labor. Robotic surgical systems have also revolutionized the way surgeries are performed in house. A robotic arm system was quickly superseded by a more sophisticated one that is a precursor of one enjoying more widespread use in surgical telemetry.

The clinical engineer, with various information sources available, is becoming an unofficial bio-informatics officer. With our participation in the institutional review board (IRB) process in-house; the technology acquisition process; hands-on familiarity with the standard equipment used in-house; communication on almost a daily basis with our clients regarding equipment performance; keeping up with medical research and current trends; consultations with clients, manufacturers, and their representatives, the in-house clinical engineer can provide technological guidance to the future.

An engineering professor's favorite question to his students is "When is software considered obsolete?" The answer is "As soon as it is marketed." Clinical engineers need to be alert to the possibility that the product that is recommended to the hospital today will be obsolete in a short time. Clinical engineers do not need to have extrasensory perception to be able to look into the future. Being well-read and scientifically curious enables CEs to unearth information that, by itself or in various combinations with other technologies, can help to paint a picture of what is to come.

Evaluating Designs for Efficiency and Reliability

When assessing efficiency and reliability, the CE should have the actual device, its user, service manuals, and an in-service from the manufacturer's representative. A block of time should be set aside to operate the device, while becoming acquainted with its various features and capabilities. This opportunity to learn new technology is quite often stimulating and enjoyable for the CE. Assessing a product's efficiency and reliability, long before it is used, need not be a guessing game. If the product's design and technology are relatively new and untested in the market, the CE looks at the manufacturer's reputation and record of accomplishment for similar products. The authors prefer devices that have been on the market for at least one year. Problems occurring in this one-year introductory period would appear in manufacturers' recalls, warning letters, ECRI Hazard Alerts, and the FDA MAUDE database.

The manufacturer's representatives usually can provide the CE with a list of user hospitals in the region or in the entire country. Checking with these users usually provides one a good insight into what to expect from the product, especially if one communicates with all levels of users and maintainers in the hospital. This is where membership at the local biomedical engineering society or any similar professional groups can be of great help.

Minimizing User Errors through Ergonomics in Device Design

Elegant design often relies upon the KISS ("Keep It Simple, Sweetheart!") principle. The design should make the equipment intuitive, simple, and easy to use. The fewer controls for staff to manipulate, especially during procedures, the better. All critical controls should be on the front panel and not susceptible to fluid spills, which is a constant risk in the hospital setting. Operating the equipment should eliminate, as much as possible, steps that are unnecessary and consolidating those that are similar and that may require a modified sequence of operation. Going beyond the equipment itself, make sure that the supporting infrastructure is available in the areas in which it will be used. A simple oversight can lead to terrible delays, not to mention costs and frayed nerves, as well as having to install or customize the facility to accommodate the equipment's needs.

Criteria for Involvement

Clinical engineering services are provided in response to the following conditions:

- Requests by human investigation committee (HIC) or institutional review board (IRB)
- Requests by medical staff
- Requests to meet a "critical" patient need
- Humanitarian use devices (humanitarian device exemptions)

Requests by HIC or IRB Investigational devices are evaluated for safety and efficacy prior to use in the hospital as part of a study, usually as part of the FDA premarket

approval (PMA) process. Less frequently, the CE department assesses devices that designed and constructed by in-house staff.

Requests by Medical Staff Often, doctors return from conferences brimming with ideas and requests to introduce new products into the hospital. Where the products show promise of being more cost-effective without compromising on safety and efficacy, they become the subject of extensive CE evaluation and clinical trials. Through this mechanism, beneficial, innovative technology can be made available to the patient population.

Meet a "Critical" Patient Need At times, the caregiver or the clinical engineer conceives of ways to customize or to modify a device to expand its capabilities, thus providing more benefit to the patient and possibly to the user. The clinical engineer possesses the education, intellect, skill, and training to perform such customization or re-engineering of a device. Such modification typically requires that the CE expend time in research. The following example illustrates the way the CE does engineering. For certain procedures, OR patients must be positioned on their side, with their arms on the side in parallel fashion. Standard arm rests that clamp onto the OR table do not allow this positioning. Alerted to this clinical need, the CE working with the OR staff conceived of a double-decker design. Some research revealed that the local armrest manufacturer sold modular components. A double-decker armrest was created from modular components. In-house manufacture of a specialty device such as this would not have been cost-effective and would have required extensive time to design and prepare mechanical drawings. Even with the aid of computer-aided design (CAD) software, preparing the necessary drawings for an instrument maker to follow would have been prohibitively expensive. In this case, the use of standard modular hardware in a novel configuration accomplished the objective at a minimum expense.

Humanitarian Use Devices (Humanitarian Device Exemptions) Humanitarian use devices are exempt from normal FDA 510(k) and PMA processes. The FDA allows the use of such equipment on a limited number of patients where the product might be their best hope (hence the term "humanitarian device exemptions"). The hospital usually treats devices of this sort as investigational and processes the introduction of this technology by way of the IRB. Under the HDE, such devices need not go through the rigorous evaluation that the clinical engineer, as a technical consultant to the IRB, must perform. However, an assessment of its safety and efficacy must be weighed against the possible benefits that the product can bring to the patient. In most cases, the risk of patient injury is far outweighed by the alternatives; e.g., permanent disability or death of the patient if he is left untreated.

Redesigning or Customizing Medical Devices

Improving Ergonomics

Not all products come customized to a user's personal specifications. By helping to improve the ergonomics of equipment, the CE can help the clinician to perform a better job more safely. Because medical devices are regulated by the FDA, care must be exercised to ensure that specifications are not altered in such a way as to conflict with these regulations. Modifications are typically limited to helping improve a product's ergonomics and do not necessarily change its specifications or performance. Examples of such modifications include the following:

- Mounting an electrosurgical unit (ESU) on a wheeled cart at waist-level height, so that a 5'2" doctor to operate comfortably
- Providing a padded armrest and a comfortable chair for a surgeon who is reconstructing a patient's middle ear
- Selection of foot-pedal controls to prevent accidentally stepping on two pedals at once
- Placing foam pads to protect a surgery patient from pressure necrosis and decubitus ulcer formation

Some in-house designs have been patented, but for the most part, the CE makes these adjustments based on need, without regard to commercialization (see Chapter 82).

Prototyping Designs to Fill Specific and Specialized Needs

After producing mechanical drawings with CAD, the next step is to render the design into a working prototype. Many times, theory does not readily match reality. Engineers should be prepared to encounter the familiar *Murphy's Law*: Anything that can go wrong will go wrong. However, with a bit of persistence, a final design is rendered, and the finished product is executed in collaboration with the machine shop or instrumentation shop. After the device is deployed, care must be taken to monitor closely the product's safety and effectiveness. Close consulting with the clients greatly helps to perfect the finished product.

Typically, the cost of such device-design activity is built into the general operating fund for the hospital. Where the project involves a research or an activity with funding other than by the hospital, the CE department bills the grant or source of funding through the client department. This funding mechanism will differ among institutions.

Should a device design progress to the stage of patenting, the department could realize some financial advantage by selling the rights to manufacture the product. The transition from device design, to patent, to manufacturing, to marketing and sales is long and costly, requiring substantial financial resources and device development infrastructure. Nevertheless, patenting can be an effective way to preserve the rights of the inventor to some remuneration from the invention.

Design/Ergonomics

Increased attention is being paid to ergonomics and human factors in medical device design (see Chapter 83). Increased efficiency and reduction in human error are achievable

using an ergonomic approach in equipment design. For example, minimally invasive surgical procedures made possible by ergonomically designed endoscopic instrumentation has reduced (or, in many cases, eliminated) the need for an open incision, thus reducing surgical time and expense and improving patient outcome (e.g., less anesthesia and reduced chance of infection). Robotic arms now extend the surgeon's precision beyond unaided physical capabilities. Lengthy surgeries lead to physicians' tired muscles, but when translating motions into action, robot helpers can eliminate the tremors of a tired surgeon's hands. Years can be added to a surgeon's career by enhancing his senses. The patient population ultimately benefits from the prolonging of a skilled surgeon's longevity.

Documenting

A well-written report can be effective in impressing upon the hospital and clients the clinical engineer's thoroughness, knowledge of the subject, and grasp of the issues involved. Writing reports helps the CE to understand more thoroughly what was accomplished in the evaluation, clinical trial, or device design. Putting thoughts into words forces one to consolidate thoughts and to communicate in a logical, understandable fashion for the target audience. On occasion, in the process of writing, various issues, options, and alternate solutions emerge that were not considered during the progress of the work. The CE should never underestimate the power of the written word. A clinical engineer's responsibility in this endeavor is to be careful and deliberate in arriving at conclusions and recommendations and to be astute enough to modify them as new information becomes available. Preparing a well-written report can induce a customer-satisfaction response that exceeds financial reward. A satisfied customer will regard the engineer highly and will seek help in the future. Furthermore, the customer is likely to recommend the engineer to colleagues.

A clinical engineer's good work is only helpful when it is communicated properly to the correct audience, who can act on the findings and recommendations. Good communication skills require that the author know the intended audience and phrase words accordingly. In the hospital, the CE's reports are usually directed to the administrators, managers, the nursing staff, and the medical staff. These different audiences require slightly different approaches that match their expectations, training, education, and experience. A layperson's approach works well with nonmedical persons. The scientific approach appeals to the clinical professional. The nursing staff seems to respond well to reports that address protocol or standard procedures for its areas of responsibilities. Doctors, by virtue of their extensive scientific education and training, respond well to a reporting style used in medical textbooks and journals. With a mixed audience, if recommendations particularly affect one group, the reporting style should be slanted in that direction. Another option is simply to write two or three different reports to send to the different groups.

Product Improvements

Clinical engineers are uniquely positioned and qualified to recommend to manufacturers device modifications that help to improve the safety and effectiveness of their products. Such modifications could be simply adding warning labels or changing existing warnings to make them more effective. Many product improvement ideas stem from work per-

formed during engineering investigation of medical device variance reports, engineering evaluations, and clinical trials.

Clinical engineering in the hospital should not be limited to recommending and implementing changes in medical devices and systems. The clinical engineer has much to offer in helping clinical staff to modify protocols and other standard procedures to improve safety, efficiency, and the effectiveness of the equipment used. For example, recommending the use of split return pads when using ESUs and advocating for smoke evacuators in the OR where ESU is used, are two measures that enhance patient and staff safety.

Conclusion

The hospital-based clinical engineer is in a unique position to advance patient care through engineering skills. Engineering is the process of synthesis and design, the creation of something that was not there before—something that fills a need. The need for good clinical engineering abounds in today's health care organizations. The clinical engineer should not be content with the role so often cast by well-intentioned, but inadequately informed, fellow health care professionals. Although some engineers think of device modification and design as merely offshoots of the job of maintaining hospital medical equipment (a view more in keeping with the education), experience and skills of an engineer is that analysis and synthesis is the main stem. Caceres (1980) would be delighted to know that clinical engineering has emerged from the shadows of the distant repair shop to the bedside where engineering skills can be most effectively applied.

Acknowledgment

As staff clinical engineers assigned to different hospital department clients, the authors did a lot of collaborative work, which helped to forge a warm friendship. We acknowledge each other's support and encouragement during this professional affiliation. We have supported each other through many rough bumps and have celebrated each other's career successes. As with most everything else, all good things must eventually end. Although two of the group have left for positions in other institutions, we thought it fitting to assemble in this chapter some collective thoughts on the role that clinical engineers can play in the hospital, with an emphasis on the design and redesign of medical devices.

Medical Device Research and Design

Åke Öberg
Linköping University
Linköping, Sweden

Engineers who are active in the health care sector have great opportunities to contribute to long-term quality development by developing new techniques or improving existing ones. By working daily with commercially available medical devices and observing ways in which products are used in practice, the clinical engineer (CE) gains valuable knowledge that, when coupled with keen insight and creativity, can lead to ways to improve existing techniques or to solve long-standing problems. The CE has a perspective on developmental requirements, which is an extremely valuable attribute in order to function as an innovator. Furthermore, the CE's proximity to the point of health care delivery provides ample opportunities for the testing and trial of new products in the end-user environment. In the pursuit of improvements in health care, many with expertise in the medical sciences (e.g., doctors, nurses, and therapists) collaborate well with engineers, for they understand the engineer's gifted ability to analyze problems and synthesize solutions. The beneficial result of such analysis and synthesis, the warp and weft of the engineer's mantle, is invention, the creation of something useful; e.g., an object, a machine, or a technique, that did not exist before.

Clinical engineering was born from the concept that engineering attributes (i.e., the analysis and synthesis) are needed to improve health care (Caceres, 1980). Over the last two decades, however, the pendulum has swung and paused over the repair-shop and financial spreadsheets. Mercifully, it is swinging back to its original position, the bedside, the point of care delivery (see Chapters 11 and 138), with no small impetus imparted by recent revelations of inadequacies in the so-called health care delivery system (Kohn et al., 2000). Regulator demands and financial pressures have absorbed and redirected time and talent, thus denying clinical engineering departments the resources for time-intensive product-development activities. Available personnel must resolve the immediate daily tasks such as keeping the hallway clear of equipment, fixing broken infusion pumps, and entering no-problem-found codes in the computer. Inventions and technical development work fell to the lowest rung on the departmental priority ladder. Sadly, hospital administrators underutilized or spurned the talents of even highly competent, well-educated, and skilled clinical engineers, often out of ignorance of their enormous potential, but also in part because of the inability of CEs to articulate their value and to advocate their profession.

The need for improved or new products for health care is the major driving force for innovations and industrial production of medical devices. New medical products are born in the light of new clinical requirements and new technical possibilities. To be able to identify the new needs and possibilities requires a high degree of competence in both the engineering and medical fields.

Developing new products takes time. A 5- to 10-year period from inception to commercialization is not unrealistic. The interpretation of marketplace trends is important in successful product development. Two main questions arise: Where will health care be 10 years from now, and which new techniques will emerge in the meantime? The needs that one sees today will not necessarily be the same 10 years from now (see Chapter 142). To correctly assess future trends and needs is of the utmost importance in the development of new, commercially successful products. The world market for medical and health care products is worth approximately \$150 billion, of which pharmaceuticals represent \$100 billion; the remaining \$50 billion represents instrumentation and medical devices (OECD, 1992).

Today health care and the biomedical industry use highly sophisticated technology in their products. It is reasonable to assume that technological progress will find early and advanced applications in the health care field. Therefore, it is of interest to discuss personal qualities and knowledge that are prerequisites for the CE who wants to engage in, and to be dedicated to, innovation activities and product development.

From Inventor to Innovator

An innovation is defined as an invention that has been successfully marketed and has reached a stage of commercial success. Usually, a distinction is made between an inventor and an innovator. The role of an innovator is much more demanding than that of an inventor. An inventor is strongly focused on the technology and the technical development of the invention; the product. The inventor seldom finds invention commercialization exciting and avoids creating the contacts necessary for further business development of the product.

An inventor must learn to become a successful innovator and entrepreneur. Knowledge in the following fields is particularly important to gain:

- **Marketing**, to perform market assessments and to understand the essentials of marketing new products
- **Economy**, to do project budget plans
- **Law**, to the protection that a patent gives

The Innovator as a Person

Concepts like innovations, innovators, inventors, product ideas, and creativity are commonly used when the importance of product development is discussed. Some of these concepts are considered to be synonymous, but sometimes one needs a short and practically oriented discussion to define these concepts.

"Creativity," for example, has hundreds of definitions in the literature. In most cases, they can be summarized as "the ability to generate something new and/or useful." For others, the word "useful" can be exchanged for "interesting," "attracting" or even "selling." In the case of technical innovations, the "degree of utility" is defined as something that can be sold on the market or can be exploited financially. Within the Organization for Economic Cooperation and Development (OECD), the concept of innovation has been taken to mean a technical idea that has been realized in the form of a product, which has been successful on the market. Creativity is the willingness and ability to produce something new that is closely related to curiosity, an inherent human attribute. In addition, the inclination and the necessity to invent and to explore are deeply satisfying and rewarding activities for the inventor. Also satisfying are creating and developing new ideas and seeing solutions to problems. One reward is to see the ideas realized, a satisfaction that is similar to that of an artist over a finished painting or sculpture. Creativity is also a necessity, even a compulsion. The inventor is often obsessed by thoughts surrounding a problem. It can seem impossible not to come back to the problem repeatedly.

Creative persons might have many unique qualities, which are easily identified such as the following:

- Flexibility
- Sensitivity to problems
- Originality
- Motivation to create
- Endurance
- Concentration on the task

A visionary mind is crucial, e.g., a talent to foresee scenarios in the future. But a visionary mind is not enough. The abilities to get things done to control project development are important. The innovator must constantly draw knowledge from the wells of marketing, economics, visualization, and patent law, all of which are important in the process of developing an idea into a marketable product.

The Life Cycle of a Product

Every product has a life cycle. It is born, matures, reaches a maximal sales figure, and finally disappears from the market. The life cycle curve of a product is a well-known concept within marketing, product development, and market research (Figure 82-1). It shows the sold quantity of a product as a function of time from its introduction on the market to the time when the product no longer is marketed, and it is usually divided into phases (Ohlsson, 1992):

- **Introduction**—when the product is first introduced on a market and the first sales occur.
- **Sales growth**—when the product has been on the market for some time and the awareness of its existence spreads and increasing numbers of the product are sold.

Figure 82-1 Product life cycle curve from introduction to obsolescence.

- **Maturity**—where the consumers interested in the product have already bought it and sales no longer increase.
- **Decline**—where the demand for the product decreases.

The duration of the life cycle can vary from a few months to many decades. The life cycle curve is a useful instrument by which the future market potential for a product can be analyzed. If the sales of a particular product are studied, one usually can tell which of the phases the demand will be in, at a given moment. Usually, the introduction and development phases are more interesting than the saturation and decline phases. The future total consumption can be calculated also by means of the life cycle curve. Using today's data, the future market potential can be forecast.

Patenting and Publishing

Good patent protection is essential for anyone who wishes to exploit an invention industrially, to invest in it, and to manufacture it. The patent is a guarantee that no one else, without risking some form of legal action, can exploit the original idea for commercial profit. In order to secure a patent for an invention, it must be "new". If one places the idea before the public by means of a publication or a lecture, then patenting possibilities are voided, thus creating a high hurdle to jump in the path to product innovation.

At university hospitals and other research-oriented hospitals, there are often visible differences in outlook between the academic researchers who will publish, or give lectures on, their new results, and the innovators who will patent new ideas as a base for industrial development. Often, both groups can be satisfied by patenting first, and then publishing somewhat later. By this procedure, the publishing is marginally delayed while at the same time the great commercial value such a patent can be utilized.

Strategic Assessments for Effective Product Development

A preliminary assessment of a new product idea must always include the following considerations:

- Market analysis
- Technology assessment
- Analyses

The results from these preliminary assessments are important cornerstones in the management of product development projects leading to a commercial success. Figure 82-2 is a flow diagram showing the steps in product development, starting with assessment and moving toward patenting and marketing and production.

Market Analysis

Early market assessments will answer two important questions (Committee of Science and Technology, 1980):

1. Is there a need (i.e., a "market") for the product that is under study?
2. Is the market large enough that an investment in a development project would be profitable?

Whether developing simple or complicated technology, one should aim to gather a good overview of the market. An early and preliminary view of a potential market helps the innovator to plan for the long-range development of the invention.

Technology Assessment

Technology assessment includes analysis of problems relating to product technology as well as production technology. Product technology assessment is particularly important for medical products in the clinical environment. Of course, safety considerations are greatly important. The technical design of a medical device must comply with existing national and international standards and regulations. Accepted design principles must be used.

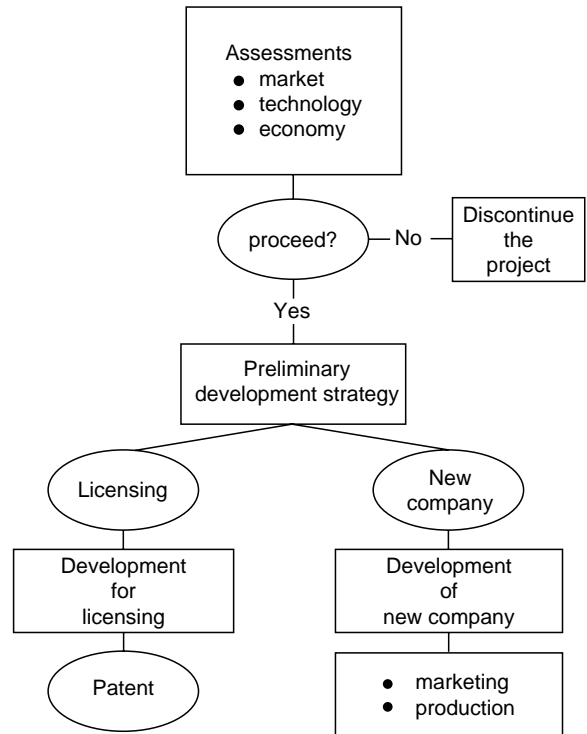

Figure 82-2 Product development flow diagram.

The involvement of external persons who are not familiar with the project is an important part of technology assessment. Such individuals are valuable for conducting tests and giving user feedback. Such an involvement often results in major improvements in the design and functionality of a device. Technology assessment of a small number of devices (e.g., 5 to 10) in "the real world" of hospitals and clinics often will affect the final design of the product in a decisive way.

Involvement of "external" persons in product assessment must include some type of protection in terms of a secrecy declaration or contract (nondisclosure or confidentiality agreement) in which the involved person is prohibited from revealing or utilizing the knowledge obtained during their evaluation work.

The assessment of production technology problems is important before mass production starts. The choice of proper production technologies can strongly affect the market price of a product. If new production equipment must be set up, then large investments might be necessary, and they would affect the economy of the whole project. If a long production run of many devices is contemplated, a production technology-oriented design will result in large savings, particularly for an inventor in a university or hospital environment, who usually does not have extensive experience in industrial production techniques. The initiation of close and early collaboration between the inventor and the final (industrial) producer of the device is strongly recommended. Such collaboration often shortens the route to the market considerably and can reduce production costs.

Economic Assessment

According to its definition, an innovation must involve financial success on the market. Thus, it is essential that the project costs are monitored regularly and that, as early as possible, an assessment be made of the feasibility of the product being a technical and a commercial success. At an early stage, only rough calculations can be made. They should be based on the cost of product sales and an estimate of the size of the product's market share that is necessary to the product being a financial success.

Concept Testing

Before starting to exploit an idea technically and commercially, an investigation should be launched to ascertain whether it really is new. A patent search often reveals that the same, or a similar, idea has been invented already. Concept testing is important for answering the following questions:

- Is the idea new?
- Does the invention infringe on another patent upon commercial exploitation?
- Can the idea be patented?
- What has been done in this area lately?

Concept testing can be carried out partly by screening patents in areas in the proximity of the current invention. A good conception of the "state-of-the-art" also can be gained by

searching databases of different types. Libraries have large databases where correctly formulated questions in the form of search profiles can give adequate guidance on innovations in the current area of work. Published scientific literature can provide interesting information on the news value of an invention. The literature can suggest the diagnostic value that is inherent in the utilization of the invention. This, in turn, is an indicator of market size.

Prototype Development

Prototype design is an important step of the innovation process. Prototype development enables one to test the strength of an idea from a technical and an economic point of view, to evaluate the response of the market, and to calculate the production cost. It is usually a long way from the prototype stage to mass production, and often it is practical to proceed in several steps:

- Sketches: Show the idea from a functional and technical point of view in terms of drawings or technical diagrams.
- Models: A three-dimensional presentation of the product idea in wood, metal, or plaster, without any functional demands. This form is especially good for marketing purposes.
- Functional model: A three-dimensional model, as the one mentioned above, but one that also can demonstrate how the idea will work.
- Prototype: The prototype is an exact model of the product as it will function and appear in mass production.
- O-series: A smaller series of the product, often used for demonstration to prospective customers, or for evaluation by experts
- Mass-produced products: Products from the production line

Forms of Exploitation

Commercial exploitation of an invention can be accomplished in many different ways. The two most usual are licensing and the starting of new companies. Licensing entails transferring the rights of the invention to an entrepreneur, who is responsible for continued development and commercial introduction. Generally, when choosing the form of licensing, the inventor has strong patent protection as a basis for negotiations with the entrepreneur. Without strong patent protection, the licensing negotiations are difficult, as it generally is the patent that, at this time, is the only meaningful feature in the negotiation. In some cases, it can be advantageous to start a new company that conducts the development work and is responsible for market launching. If the invention to be exploited concerns completely new areas where few or no established companies are active, then a start-up company for commercialization can be a quicker route to the market. After successful product development and market launching, the company can be sold. Upon starting a company, the patent issue is generally less important, while matters concerning marketing and manufacturing are more important. After the invention has been assessed from market, technical, and economic perspectives, it is time to decide on the form of full-scale exploitation.

Table 82-1 Comparison of activities on exploiting an invention

Activity	Demand	
	New company	Licensing
Patenting	less	more
Prototype design	same	same
Marketing	more	less
Manufacturing	more	less
Financing	same	same
Organization	more	less
Time span	better	worse
Risks	same	same

Often, it is the inventor's own disposition that determines the form of exploitation chosen. If the inventor is more interested in the continuous development of a new technique, then licensing (which amounts to transferring the marketing and financial problems to someone else) is the choice. If, however, the inventor finds it stimulating to work with the entire production process from technical development work through to sales, then starting a company is the choice. A clinical engineer who is employed by a hospital will find that the hospital's policy also influences the choice of form of exploitation. Table 82-1 describes differences between the two forms of exploitation:

Human Factors: Environment

William A. Hyman

Biomedical Engineering Program
Texas A&M University
College Station, TX

Valory Wangler

Biomedical Engineering Program
Texas A&M University
College Station, TX

Human factors considerations in clinical engineering address the ability of personnel to effectively use and service medical devices in a safe and consistent manner under the actual conditions found in the medical setting. The application of human factors begins with the design of individual medical devices. This area of human factors has received considerable attention, including for specific areas of the hospital, e.g., anesthesia and intensive care (Cooper, 1978; Westover et al. 1998), by individual manufacturers, and from the U.S. Food and Drug Administration (FDA) and professional organizations (ANSI/AAMI, 2001). The attention of manufacturers and the FDA is primarily on the individual device because that is what is being designed and regulated. Extending beyond the individual unit, human factors considerations also must be applied to the assemblage of equipment in the clinical setting. Thus, the first component of the environment to be considered is that of multiple medical devices being placed near each other and simultaneously used. The next level is the multiple patient environment, where the use of several different sets of devices on patients in close proximity to each other adds to the overall equipment complexity. Further extending the perspective, the physical environment also has human factors issues, as does the personnel environment. Ultimately, the management system and associated policies and procedures also have human factors components. Thus, human factors must be applied at several levels of design and management in order to achieve the ultimate goal of medical devices being consistently used in a safe and effective manner.

The System Problem

The need for the effective application of human factors is consistent with the Institute of Medicine report's (Kohn et al. 2000) emphasis on medical errors being an important issue in the delivery of quality of health care. This report, and both earlier (Shepherd and Brown, 1992; Bogner, 1994; Leape, 1994) and subsequent (Becher and Chasin, 2001) work, emphasizes that errors are usually a result of a combination of factors, often involving multiple instances of less-than-adequate human or system performance in a complex world, rather than a single error by a single person. Such errors have been called "organizational accidents" (Reason, 1997) to distinguish them from truly individually induced accidents. While the majority of such attention has been focused on medication errors, surgical errors and medical device use have also received attention. Thus, it is not just one device that requires attention to human factors but also that device in the context of all of the devices in use, in the actual physical environment of use, as used by a combination of personnel, most of whom also have multiple other duties.

Human factors Issues for Individual Devices

The underlying principles of the application of human factors to the design of individual medical devices are that humans have a variety of physical, psychological, intellectual, and motivational attributes and that devices must be designed so that challenges to the capacity these attributes is minimized or eliminated. Thus, vision, perception, hearing, reach, strength, fatigue, common expectations, and other realistic performance capabilities must be considered during design. These must be considered for normal operating conditions and a variety of abnormal conditions and emergencies. They also must be considered for all of the users including installers, clinical and centralized set-up and maintenance, repair, and direct patient care. People make mistakes, and many of these mistakes are predictable based on general and documented experience. Similarly, there is a common group of contributing causes to such mistakes. Based on this knowledge, it is inappropriate, and potentially dangerous, to design equipment assuming perfect user performance at all times. Herein lies the basic contribution of effective human factors design—it is the bridge between a device that is technically capable of achieving the desired outcome, and the actual and consistent achievement of that outcome under the actual conditions of use, by the real users.

Device Interactions

Medical devices have the potential for adverse technical interaction (Miodownik, 1993). Well-known examples of this are the early vulnerability of monitoring equipment to defibrillator discharge, laser-induced tracheal tube fires (de Richemond and Bruley, 1993), and the incompatibility of oxygen and aluminum regulator valves (NFPA, 1999). In addition to technical interaction, there is a human factors interaction. A single problematic device can adversely affect the use of other devices because of the problematic device distracting or occupying the user because of the excess attention it requires. In addition, frustration and related adverse responses can generally degrade overall user performance. The reverse situation also occurs in which a "user-friendly" medical device allows the user to accomplish quickly, efficiently, and accurately tasks associated with its use, increasing time available for other duties, including the use of the other equipment. Well-designed equipment also positively affects the user's overall experience and sense of being in control.

Another aspect of device interaction is general clutter presenting the opportunity for multiple displays, tubes, and cables to be confused with, or masked by, each other. The general principal that displays should be logical and user-friendly in order to facilitate the finding of needed information is well established (Wickens et al. 1998). Some actually take pride in the complexity of the intensive medical environment, as opposed to recognizing that a collection of various devices from various vendors that are physically placed with, in some cases, limited thoughtfulness would not be acceptable in many other high-tech industries. Even the use of a single vendor for multiple devices does not ensure a reasonable final assemblage of devices. The ability to stack monitoring devices, while useful, does not automatically provide reasonable system integration. Those individuals should ask themselves whether they would want to fly on a commercial airliner if they saw that the cockpit was a conglomeration of individually acquired and placed instruments with cables strewn between them.

The lack of standardized color-coding (or any color-coding at all) of the function and connection points of various tubes and cables has been surprisingly resistant to improvement. Even the physical placement of multiple devices is a challenge at the clinical level with respect to location, access, and view. Also problematic when multiple devices are used together is the increasing number of displays and user-adjustable parameters, each coupled with a variety of display formats, e.g., analog, digital, and strip chart, and a variety of user interfaces, e.g., rotating knobs, sliders, and up/down buttons. Problems with multiple alarms have also been identified, including too many identical or similar sounds and inconsistent hierarchies of the criticality of sounds, combined with the challenge of locating some kinds of sounds in space, or otherwise identifying which parameter of which device (let alone what condition of the patient) is causing the alarm. Multiple simultaneous alarms compound the challenge. The psychophysiology of sound detection in terms of volume, frequency, and other parameters has been studied (Wickens et al. 1998; Malkin, 1991) but not adequately applied to the medical environment.

Look-alike devices that perform different functions, or that are not as interchangeable as they appear to be, provide another form of potentially dangerous device interaction. Various patient cables that have the same (or not quite the same, but physically interchangeable) connectors at the device end, but that use the conductors in different ways, and endoscopic dissection balloons that look essentially identical outside the body but that provide a different inflation field are two examples of such look-alike devices. Programmable devices also look identical but can perform different functions, depending on the way they are set-up. Control of these potential problems includes rigorous identification of such devices, avoidance of their presence in the hospital through purchasing decisions, post-purchase labeling to add further device identification, and focused training of personnel who are likely to encounter both devices. Training is generally considered the least desirable way to address a hazard that requires control.

The Multiple Patient Environment

Human factors challenges with respect to the use of multiple devices on a single patient are compounded when several patients are receiving care in close proximity to each other. Here, the physical and visual complexity is compounded, and the setting can be so crowded that the devices are physical barriers to care. In addition, as the number of devices used increases, the numbers of parameter settings, displays, and alarms increase proportionally. However, the number of personnel does not generally increase in direct proportion to the number of patients, so that the ability of a nurse or other direct caregivers to perform optimally with respect to each individual patient can be compromised, especially during one or more emergency conditions.

The Physical Environment

Physical environment issues include those associated with the placement of one or more medical devices, and their various patient and other interconnections as discussed above. In addition, lighting, sight lines, noise, temperature, and other environmental parameters can aid or inhibit the safe and effective use of medical equipment and, therefore, the quality of care. Lighting can be too bright or too dim (Wickens et al. 1998; Bridger, 1995). Bright lights can interfere with the ability to read displays effectively, and the homemade glare-reducing shade is still to be found. Continuous bright lighting has an adverse effect on patients. Dim lighting obviously can interfere with the ability to observe unlit or inadequately lit displays or to detect other adverse medical device or patient situations. The color spectrum of patient lighting can affect visual detection and interpretation of the patient's appearance. The general aspects of lighting requirements and effects can be found in a variety of resources (e.g., Bridger, 1995).

Sight lines are important with respect to the ability to read some kinds of displays, especially in the case of screens that have a narrow useful-viewing angle or that are partially obscured by antiglare shades. Displays at substantially different distances from the viewer can further challenge those using different glasses for different tasks and those whose focal distance no longer adjusts as rapidly as it once did. Even if technically viewable, wide or inconvenient placement of multiple displays requires a scan strategy that is rarely, if ever, taught or discussed. The arrangement of multiple displays with respect to relative importance and need to access should be practiced as well (Wickens et al. 1998). The default condition is that displays will not be routinely scrutinized if they are not easily viewable. Another sight-line issue is the ability to see a patient, or multiple patients, from one or more workstations. Even specific periodic visual observation of a patient cannot ensure that serious adverse events will not occur. While one-on-one, continuous, direct observation of all patients is not feasible, or even indicated, there must be a deliberate system in place to make specific observation-requirements decisions for each patient. Moreover, violations of such guidelines because of inadequate staffing are not acceptable. The use of monitoring is not a panacea for the problem of patients who are out of sight. To be effective, the mode of monitoring must be specifically relevant to the medical condition of the patient and must cover all likely or anticipated adverse events. The provision of less-than-adequate monitoring has the psychological risk of leading the caregiver to believe that the monitoring will bring their attention to a wider, and generally unspecified, range of adverse conditions. Therefore, vigilance can be degraded, rather than enhanced, by monitoring. The question of when, if ever, monitoring can be a substitute for direct attention is an open one, although manufacturers tend to advise that their monitoring equipment not be used in this fashion. Thus, risk management attempts by the manufacturer can shift to the hospital the responsibility for monitoring related adverse events.

Noise pollution has two components. One is the direct effect of environmental noise on the ability to hear or distinguish important sounds emanating from medical devices, or even from patients. As discussed above, distinguishing significant device sounds, such as alarms, can be difficult even under ideal conditions and is surely degraded by excessive noise. The second component of noise pollution is its generally disturbing nature, at least to some people, including both staff and patients. Annoyed people are not likely to perform at their best, and therefore a particular real environment might not produce the same level of performance as other actual or simulated environments.

The effect of temperature and other environmental annoyances and discomforts is hard to document, but under routine circumstances, people are believed to work best when their comfort level is enhanced, especially over long durations, as opposed to their ability to respond to crises, which might be unaffected by adverse external influences. Environmental air and chemical hazards must be addressed, of course, for both direct safety and human performance.

Personnel

Ultimately, it is the staff in the hospital who determines the quality of care, including the safe and effective use of medical devices. Similarly, medical error is essentially a human problem and therefore is within the domain of human factors. Any hospital's staff reflects a range of education, training, experience, motivation, distraction, and personal stress. Inadequately trained personnel cannot be expected to function consistently at a high level, especially when confronted with unusual or stressful situations. Of particular relevance to medical devices is the distinction between knowing generically how to use a type of medical device (e.g., an infusion pump) and knowing how to use a particular manufacturer's brand and model of that type of device (e.g., brand X, model Y infusion pump). Even devices that were originally identical can perform differently if there are user- or technician-selectable options. This issue can be difficult to address when temporary nurses are employed, either from outside the hospital or from a different department. Here, the lack of standardization of important features between devices from different manufacturers, which might be reflected even within a single hospital, makes

such distinctions particularly important. Motivation is also a variable factor. At the worst extreme is deliberate adverse behavior. Presumably, this is not a common event. The broad middle ground can include a range of personal and institutional disgruntlement that results in degraded performance, as compared to an individual's underlying ability. This is perhaps a perfect example of the human factors issue. The individual is generally capable of achieving the desired outcome, but, for one or more reasons, does not.

Stress, whether personal or work-related, is another adverse factor that can interfere with one's ability to achieve what one otherwise would be capable of achieving. Ideally, people would be stress-free, or at least they would be able to isolate stress from their on-the-job performance. However, the world is not ideal, and any tacit or explicit assumptions that one makes provides an opportunity for adverse consequences. In hands-on health care, both the demands of the job and the potential for disaster are high, in contrast to many office jobs, for example, where an individual under self-identified stress can choose to do relatively little on any particular day, and any work that is attempted has little potential for personal injury. A systems approach first must design the work to minimize stress-related failures (O'Neil, 1998), must have a means to consider whether staff members are not capable of fully performing their duties, and must have a nonpunitive means to encourage such self-identification, at least on an occasional basis.

The adequacy of hospital staffing (i.e., the number of people and their skill levels) has been a particular issue during the managed care cost squeeze. Many hospitals have downsized their staffs and/or have replaced highly skilled positions with less-skilled, less-costly, personnel. Having more patients to care for, more equipment to manage, and more paperwork to do has a limit before performance is degraded. In most organizations, the staff rises to the challenge of doing more with less, thus appearing to reward the decision makers. In addition, a period of downsizing is not an opportune time to complain about any potential, but not realized, negative impacts. Furthermore, systematic studies of the impact of such decisions are not routine. However, selected studies have revealed the obvious. Patients do better when the staff treating them have the highest skill and experience level and are not so overworked that they cannot apply these skills in a conscientious and timely manner.

Clinical engineering departments have faced these same pressures with the additional threat, and reality, of the entire department being outsourced to reduce cost. Such cost reduction implies either that the old organization had bloated salaries or that the new organization is more efficient than the old one because of higher technician productivity and less waste, or that the new organization will provide fewer services than the old one did. The latter explanation often can be attributed to the fact the total services provided by an effective clinical engineering department cannot be explicitly found on a list of functions and duties, yet provide real, value-added service (Hyman and Cram, 1999). When only the enumerated duties are outsourced, those that were not enumerated are likely to disappear.

The Management System

It is sometimes possible for good people to overcome inadequate management and inadequate resources. However, it is best if the management system is a good one that has clear knowledge of the challenges and that assures resources and controls that address those challenges. While it also might be possible for good management to overcome a weak staff, good management combined with good personnel is the key to success. This includes an understanding of human factors issues across the spectrum outlined above. It also requires strong support for the need to include human factors considerations in all aspects of the selection, use, and maintenance of medical equipment. Finally, adverse events with use-related errors must be considered from the systems perspective, rather than from a blame-the-error maker perspective (see Chapter 55), and there must be procedures in place that require an adequate investigation of the underlying causes of device-related and other problems (see Chapter 64). At the FDA, and elsewhere, this perspective has led to the term "use error" over "user error" because the latter implies a conclusion as to what caused the event, while the former more factually describes the event.

Another important risk management requirement in this regard is an open, encouraged, and nonpunitive system of adverse, near miss, untoward, and uncomfortable event reporting. It is always disturbing to discover that one or more people were aware of device or system malperformance before it was involved in a patient (or other) injury. Reasons for not reporting might be related to fear of being labeled a complainer, or unsympathetic responses from support personnel when a "silly" question or complaint occurs. The former can be addressed by anonymous reporting mechanisms, or by providing rewards for valuable comments. Inappropriate responses to reports are a human factors issue in themselves and can be addressed by having buy-in through training as to the importance of open and uninhibited communication.

The FDA is also encouraging voluntary reports under its "Use Difficulty Feedback" program (FDA, 2003a), and reporting of certain types of medical device events to the FDA is required under the MDR regulations (FDA, 2003b). External reporting of adverse experience is also encouraged by various nongovernmental organizations such as the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) (JCAHO, 2003). Whether voluntary or mandatory, external reporting has important risk management implications with respect to the possible use of such information in adversarial legal actions associated with allegations of negligent patient injury. Therefore, it is appropriate for such disclosures to be made under suitable guidance and control.

The public, or membership-based, accessibility of the disclosures of others provides a valuable resource for identifying problems before they occur at a particular institution. Therefore, there should be a system to actively monitor such reports, to determine their local relevance, and to take steps to implement preventive actions. Merely bringing such reports to the attention of relevant staff members is generally not effective and will serve only to demonstrate that the problem was known before it manifested itself. There must always be an assignment of specific responsibility to assess and to resolve the issue, and a systematic review of that assessment and resolution.

Summary

Human factors cover a broad range of issues, from the design of individual medical devices to the design of management systems. It addresses the fact the people are less-than-ideal performers at their best, and variable performers over time. Consequently, people make mistakes or otherwise perform on occasion inadequately. Fortunately, most lapses are benign, but on occasion they can lead to patient, user, or bystander injury and/or damage to valuable equipment. It has always been tempting in these situations simply to blame the individual, and to admonish them to focus and do better, perhaps to send them to a retraining session, to terminate them if the situation was grievous, and then to consider the event resolved. The more modern systems-oriented view requires, at a minimum, an investigation of why the individuals were in a situation of not performing to their capacity, and, in particular, what it was about the situation, the equipment, the environment, and the system that might have contributed to degraded performance, and what steps can be taken to correct the causative chain or to provide safeguards against the causative chain reaching the adverse endpoint. Of course, it is also necessary to implement these steps.

Medical Devices: Failure Modes, Accidents, and Liability

Leslie A. Geddes

Showalter Distinguished Professor Emeritus of Bioengineering, Purdue University
West Lafayette, IN

This chapter addresses the three types of medical devices and the types of malfunction that can occur. It gives a short explanation of product liability. Several examples of medical device accidents are presented. It is the objective of the chapter to assist the clinical engineer in identifying foreseeable accidents and to provide guidance on obtaining medical device standards and historical information on medical device accidents. In one way or another, clinical engineers work with three types of medical devices: Diagnostic, therapeutic, and assistive or rehabilitative.

The diagnostic device acquires information for presentation to the human senses. In essence, the diagnostic or data-acquiring device is an extender of the human senses. It is in this area that transducers and display devices play key roles. The therapeutic device is used by the physician, or the physician's delegated representative, to arrest or control a physiological process that has gone awry because of disease, trauma, or some other agent. Although chemical agents (drugs) are most prominent in the therapeutic area, physical devices, such as the high-voltage X-ray (to kill cancer cells), the pacemaker (to initiate rhythmic heartbeats), or the defibrillator (to arrest the lethal cardiac arrhythmia, ventricular fibrillation), are but a few prominent examples of therapeutic devices. Assistive or rehabilitative devices are used to make up for diminished function or to provide for a lost function, often when a disease process has been arrested but a deficit remains. Some of these devices might be life-supporting or life-sustaining. The objective of many rehabilitative devices is to make the subject capable of being self supporting, thereby allowing him or her to do things without reliance on the help of others.

Failure Modes

Although well designed, well made, and closely regulated, the three types of medical devices can fail and cause injury, property damage, or death to a patient. Examples and

the legal aspects (product liability) will be discussed below; but first it is useful to identify at least some of the failure modes and consequences that can accompany the use of these three types of medical devices.

Diagnostic Devices

- Provide inaccurate information leading to inappropriate medical decision and action
- Malfunction or give erroneous information due to environmental effects
- Are sometimes used for other than the intended use
- Are hazardous or injurious to the patient due to component failure or due to excessive leakage current because the device is not grounded properly
- Are hazardous due to multiple devices connected to the patient (device interaction)
- Fail when alarm is turned off
- Can cause an allergic response when in contact with the body

Therapeutic Devices

- Failure to deliver adequate or delivery of excessive therapeutic agent
- Lack of indication that therapeutic agent is being delivered
- Delivery of inappropriate therapy
- Inadequate training or experience of the operator
- Failure to heed warnings in instruction manual
- Failure to read instruction manual or package insert
- Allergic response to therapeutic agent or delivery system
- Interaction between multiple therapeutic agents or multiple devices connected to same patient
- Susceptible to malfunction due to environmental agents (e.g., EMI, noise, ultraviolet rays, heat, or humidity)

- Drug synergism or antagonism
- Adverse interaction between two or more therapeutic devices connected to a patient

Assistive or Rehabilitative Devices

- Patient inadequately informed or trained
- Failure to report for checkup
- Device inadequately protected from environmental agents (e.g., EMI, noise, vibration, heat, moisture, and ultraviolet rays)

Product Liability

The term “product liability” describes the litigation in which a complaining party (the plaintiff) alleges that a product caused personal injury, death, property damage, and compensation is sought for the loss from one or more parties (the defendants), who usually include the manufacturer, contractor, assembler, distributor, vendor, and/or practitioner (and often assistants) who used the product. Product liability falls within the purview of civil law, and to prevail requires that proof be established by a “preponderance of the evidence.” The dictionary definition of “preponderant” is “superior in weight, number, or power.” One loose definition of adequate proof, under this standard, would be “more likely than not.”

Product liability extends into three areas: Manufacturing, design, and misrepresentation. To prevail, a plaintiff must prove that the defect existed when the product left control of the manufacturer or vendor; the provider knew (or should have known) of the existence of the defect; there were feasible alternatives that would have eliminated the risk; and the product caused the injuries or damages complained of. Misrepresentation involves making untrue claims about a product. See Chapter 127 for a detailed discussion of product liability.

Product Defect

Legally, a product is defective when it fails to meet the provider’s own specifications and applicable industrial and/or governmental standards. However, meeting the requirements of such standards is not enough; it must be shown that the product is safe for any reasonable and foreseeable use. For a product to be found to be defective, the plaintiff must prove that the defect was present when the product left the manufacturer’s premises. Because a product might pass through one or more vendors, proof of when the defect was induced can be difficult. It is for this reason that the vendor(s) and the manufacturer are often named as codefendants in a product liability lawsuit.

Inspection and maintenance records are very useful in showing that a product was or was not defective. Manufacturer’s instruction manuals often specify the type and frequency of these activities. However, if the maintenance is performed by unauthorized personnel, the manufacturer’s warranty becomes void, and the manufacturer cannot be held responsible for any harm done by a defective product.

An improvement (however useful) in a product by the purchaser renders the product not what the manufacturer intended the product to be. This constitutes tampering, and the manufacturer cannot be held responsible if an accident occurs.

The instruction manual identifies the features, operation, and proper use of a product. It often identifies risks and hazards and cites warnings associated with use of the product. This information is often valuable in explaining the cause of an accident.

Some medical devices are leased, and it is the responsibility of the lessor to provide a properly functioning and safe product. Therefore, the lessor’s inspection, testing, and maintenance records and proof of adherence to the manufacturer’s specifications are important. Such information can be useful in explaining the cause of an accident.

All products have a finite life, and despite proper inspection, testing, and maintenance, a product can malfunction because of a component failure. In such a case, it can be difficult to establish liability. However, maintenance records can show whether a particular component has failed frequently. In many cases, reports of medical device related accidents or incidents are maintained by the FDA in a Manufacturer and User Device Experience (MAUDE) database. MAUDE should be consulted to investigate whether the same event has been reported by other users of the same product. If it has been, and if a competitor’s product does not have the same defect, then the issue of a design defect arises.

Although accelerated life testing is possible with some products, with others it is not. The best information on expected product life comes from actuarial data, i.e., the past history of a product.

One important aspect of a product defect is in identifying the consequence(s) of the defect. In other words, it is essential to show that the presence of the defect caused or contributed to the harm, injury, or death. It should be pointed out that, in some cases, harm was done that was unrelated to a product defect. One should be alert to the practice of blaming a device when improper use or negligence may have been the cause.

Misuse

When harm results from the misuse of a product, it is usually assumed that the product was without a manufacturing or design defect. Therefore, the issue becomes one of foreseeable user behavior. The U.S. Supreme Court has held that foreseeability is significant in product liability cases when the product is what it is intended and known to be, but injury was suffered because the product was misused. A product is not misused merely because the manufacturer intended that it be used in a different manner; the manufacturer must show that the use that caused the injury was not reasonably foreseeable. Therefore, the manufacturer is responsible for designing a product with reasonable, foreseeable misuse in mind. It is in this area that the instruction manual can play an important role by identifying the best procedures, intended use, and potential for injury in the event of misuse.

There are two types of misuse: Contributory negligence and assumption of risk. In the former, the test of reasonableness applies. In other words, did the user act as a reasonable

person in the same or similar circumstances? In the latter, the assumption of risk is evaluated on the basis of what the user knew, just before the incident. In assessing the assumption of risk, there are three elements that the plaintiff must show, on the part of the user: That the user knew of the risk before the incident; acted voluntarily; and acted unreasonably.

One should always bear in mind that tampering or sabotage could have occurred, and thus might have been the cause(s) of an accident. “Tampering” is defined as meddling for such purposes as altering, damaging, or misusing something. “Sabotage” defined as is malicious injury to work, tools, machinery, or other items in order to cause malfunction.

Negligence

Negligence is the failure to conform one’s conduct to that of a reasonably prudent person under similar circumstances. If such conduct failure results in harm to a person (or property), a lawsuit can be filed. The purpose of negligence law is protection from unreasonable risks or harm, which are foreseeable and therefore preventable. To prevail in a negligence lawsuit, five elements must be proven: The existence of a duty of care; breach of that duty; proximate cause (or “legal cause”); actual cause (or “cause-in-fact”); and actual harm or injury (i.e., “damages”).

“Duty of care” refers to behavior as a reasonable and prudent person; breach of that duty involves showing that something has happened and that the defendant acted unreasonably under the particular circumstances. “Proximate cause” refers to identification of the reason for the accident. “Damages” refers to details like the value of personal injury, property damage, emotional stress, or lost wages that resulted from the negligent behavior.

Design Defect

A product does not have a design defect when it is safe for any reasonably foreseeable use. Such a safe product also has met all of the applicable functional specifications. Before a design defect can be alleged, it is necessary to establish that the product has met all applicable manufacturing, industrial, and governmental requirements, and that despite the manufacturer having met these requirements, the harmful incident occurred.

To establish that a design defect exists involves the following elements:

1. Identification of the design defect
2. Establishing a link between the design defect and the harm done
3. Identification of alternate designs that would have prevented the harmful incident
4. Comparing the product performance with like products offered by other manufacturers

One good example of a design defect is a product that functions normally in one typical environment but fails in another. In such a case, the injured party can raise the issue of a design defect. For example, if an apnea monitor operates properly in one environment (e.g., in a hospital ward), but fails to alarm cessation of breathing in another environment (e.g., the home), the issue of design defect can be raised. If the reason for failure were electromagnetic interference (EMI), it would be fruitful to inquire whether similar apnea monitors provided by competitors also have failed in the same environment or a comparable environment. If they have not failed in both environments, it shows that technology that can eliminate this hazard is available. If the manufacturer of the monitor that failed was unaware of, or chose to ignore, the available technology, a case for a design defect can be made.

Medical Device Accidents

Accidents can be associated with the use of diagnostic, therapeutic, and rehabilitative devices, and the clinical engineer might be called upon to investigate. The investigative procedure is embodied in the saying “When you hear hoof beats, think of horses, not zebras.” In other words, look for the simple and obvious things first. A few examples of device malfunction are presented below. Additional information on accident-investigative techniques for the clinical engineer can be found in Bruley (1994), Dyro (1998, 2003), and Geddes (2002).

Diagnostic Device Accidents

As stated earlier, the diagnostic device presents information to the human senses. One frequently used diagnostic device is the pulse oximeter, which measures the redness of the blood. The reading that it provides is termed “oxygen saturation” (S_pO_2); however when this quantity is measured with the pulse oximeter, the notation used is S_pO_2 . Typically, the finger, toe, or ear is the site for measurement.

Murphy (1990) describes an unusual accident that occurred with a pulse oximeter: “A 4.4-kg, full-term infant was born by vaginal delivery with the aid of vacuum extraction. A subcapsular occipital hematoma developed, and the patient was transferred to the newborn nursery. All the nursery’s pulse oximeter probes (manufacturer A) were in use, and a probe (manufacturer B) was borrowed from the anesthesia department. The nursery personnel connected the probe on the infant to the A machine. Initially, a wrap-around finger probe was applied to the right ring finger, but no saturation (S_pO_2) reading was obtained. The problem was assumed to be a faulty probe. This probe was removed after approximately 1 minute and noted to be ‘a little warm.’ A second type of probe (clip-on type) was then applied to the superior aspect of the right ear pinna. After approximately 3 minutes without obtaining any S_pO_2 or pulse rate readings, the tip of the ear was noted to be acquiring a red color, the probe was removed, and further attempts to monitor S_pO_2 were abandoned. Over the next several hours, it became apparent that the infant had been burned in two locations, suffering from a second-degree burn to the right ring (and adjacent middle) finger and a third-degree burn to the tip of the right ear. The infant subse-

quently recovered uneventfully from the occipital hematoma. The burns were initially treated with topical therapy, and the patient was seen in consultation by a surgeon prior to discharge. Reconstructive surgery will likely be required at sometime in the future for repair of the right ear."

Subsequently, the authors measured the temperature at the tip of the clip-on probe while connected to the machine used in this incident. Within two minutes, the temperature at the tip of the probe was 200° F. This information was reported to the manufacturer and to the Food and Drug Administration. Was this a product failure?

The surprising thing about the foregoing incident is that the connector of one manufacturer's probe could engage the receptacle on the other manufacturer's instrument. No mention of any warnings that this could happen appeared in the manuals of manufacturers A or B. The foregoing incident raises several questions: Were the nurses adequately trained? Was there a design defect? Had the manufacturer of the probe made warning labels that indicated that the pulse oximeter probes should only be used with the instrument?

Clearly, if the nurses had had adequate training, they would not have thought that oximeter probes were interchangeable among different manufacturers' instruments. Regarding a design defect, this is unlikely. However, it would be prudent for a designer to use a connector that is different from that used by a competitor. In retrospect, warning labels should have been placed on the pulse oximeter probes and machines, and in the instruction manuals.

Therapeutic Devices

Therapeutic devices take many forms and are used by physicians or their delegated representatives. As stated earlier, chemical agents feature prominently in this category, and obvious errors can occur. However anesthesia machines can be considered therapeutic devices because they allow surgeons to perform their tasks effectively. Two examples of malfunction of therapeutic devices (infusion pump and anesthesia machine) follow.

Infusion Pump Mishaps

Drugs are often injected into the vascular system by way of a programmable infusion pump. Typically, a sterile syringe containing the drug is inserted into the pump, and the delivery program is entered by a keyboard. Such devices are typically microprocessor-controlled.

Silberberg (1993) cited the following cases of infusion pump malfunction: (1) An infusion pump changed rate when a cellular phone was placed on the instrument stand; and (2) an infusion device on an isolated circuit (high source impedance) behaved erratically because of conducted EMI at 33 MHz. Obviously, the drug infusion pump was inadequately protected from environmental electromagnetic interference (EMI).

Anesthesia Machine Mishaps

An anesthesia machine delivers a gaseous anesthetic and oxygen to the patient. The exhaled carbon dioxide (CO₂) is removed by a CO₂ absorber (soda lime) in the breathing circuit. The CO₂ absorber is in an optically transparent cylinder and contains an indicator (ethyl violet), which turns purple when the absorber is exhausted. Carbon dioxide is a potent respiratory stimulant that causes the breathing rate and depth to increase (hyperventilation). An increase in the concentration of CO₂ in the blood is known as "hypercarbia." If hyperventilation occurs when a spontaneously breathing patient is connected to an anesthesia machine, several undesirable consequences can occur, not the least of which is the inhalation of more and more anesthetic, thereby deepening the level of anesthesia, which can lead to respiratory arrest and death.

Andrews et al. (1990) reported a case of a patient hyperventilating spontaneously during anesthesia; yet the CO₂ absorber did not turn blue indicating a functioning CO₂ absorber. Fortunately, an accident was prevented because blood pCO₂ was measured routinely. It was decided to change the CO₂ absorber. Later, it was found that the CO₂ absorber failed because of deactivation of the color indicator by radiation from operating-room fluorescent lights (which emit a small amount of ultraviolet radiation), which can bleach the indicator.

Andrews et al (1990) carried out a series of carefully controlled experiments and stated that after 24 hours of fluorescent-light exposure with a received flux density of 46 mwatts/cm² at 254 nm, the concentration of functional ethyl violet remaining in pulverized Sodasorb was 16% of the baseline value. Furthermore, using multiple light sources of various intensities, the greater the intensity of light, the more rapid the rate of decline of the ethyl violet concentration. Finally, the authors pointed out that photodeactivation is more likely to occur in operating rooms (ORs) that are brightly lit or in those that utilize ultraviolet germicidal bulbs. Intensely lit ORs are the trend, and many existing ORs contain germicidal UV bulbs. This stated that end-tidal CO₂ monitoring might be more beneficial than color change of absorbent to diagnose rebreathing in those operating rooms.

It is obvious that the CO₂ absorber should have been contained in a chamber that filtered out ultraviolet radiation and allowed visible light to pass, to identify the color change when the CO₂ absorber is exhausted. Clearly, this is a design defect because technology was available to prevent the accident.

Rehabilitative Device Accidents

Rehabilitative devices are designed to make a patient more self-supporting. Some devices are life-sustaining and must not fail. One common type of rehabilitative device is the electrically powered wheelchair.

Powered Wheelchair Mishaps

Motor-driven wheelchairs and scooters used by patients contain electronic controls that have malfunctioned. Silberberg, of the FDA Center for Devices and Radiological

Health (CDRH) (1993) reported that a quality assurance manager, who had previously worked for a large wheelchair manufacturer, inquired in a letter dated June 26, 1992 about the status of medical device electromagnetic compatibility (EMC) standards. As a side issue, he stated that in his previous position he had received reports of powered wheelchairs driving off curbs and piers unintentionally when a police or fire vehicle, harbor patrol boat, or CB or amateur radio transmitter was operating in the vicinity. Silberberg had reproduced the phenomenon under controlled conditions and had observed powered wheelchairs "go by themselves" within 15 or 20 of a police or fire radio. The CDRH databases were checked for reports of electromagnetic interference problems with powered wheelchairs. While several reports of unintended motion were found (several involving serious injury), none in the report had been attributed to electromagnetic interference.

CDRH engineers investigated the EMI susceptibility of the motion controllers of several makes of powered wheelchairs and scooters. The powered wheelchairs tested were found to be susceptible to field strengths in the range of 5 to 15 V/m. At the lower end of the susceptibility range, the electric brakes would release, which could result in a hazard of rolling if the chair were stopped on an incline. As the field strength at a susceptible frequency was increased, the wheels would begin turning, with the speed of rotation being a function of the field strength.

CDRH engineers also measured the emissions from police and fire radios. A 100-watt state police radio transmitting at 39 MHz was found to have a field strength of 41 V/m at a distance of 0.9 m. CDRH also learned that a small number of manufacturers of wheelchair controllers supply much of the powered-wheelchair and scooter industry. It is obvious that the controllers used in these wheelchairs were inadequately shielded to exclude such electromagnetic interference (EMI).

Information Sources

FDA MAUDE Database

In 1990, the U.S. Congress passed the Safe Medical Devices Act (SMDA), which went into effect on May 28, 1992 and was amended with the passage of the Medical Device Improvements Act in 1992. This act, as amended, amendments mandated the reporting of all incidents associated with the use of medical devices that result in serious injury or death. Such incidents must be reported to the FDA under Medical Device Reporting regulation (MDR) Part 803 of Title 21, Code of Federal Regulations (CFR). The FDA maintains a database of problem reports called "Manufacturer and User Device Experience" (MAUDE). Such reports are available from the FDA and can be useful in establishing facts in a lawsuit. Recent FDA regulations relating to 21 CFR parts 803 (i.e., MDR) and 807 (i.e., pre-market approval) clarify and expand requirements for medical device manufacturers and health care facilities (60 FR 63597, Dec. 11, 1995, as amended at 62 FR 13306, Mar. 20, 1997; 65 FR 4118, Jan. 26, 2000).

The reporting requirements mandated by the Safe Medical Devices Act are highlighted in the following:

Health care facilities must submit a report whenever they receive, or otherwise become aware of, information, from any source, that reasonably suggests that a device has, or may have, caused or contributed to a death or serious injury.

The term "serious injury" is defined as an injury or illness that:

1. Is life threatening; or
2. Results in permanent impairment of a body function or permanent damage to a body structure; or
3. Necessitates medical or surgical intervention to preclude permanent impairment of a body function or permanent damage to a body structure

The following are required to report:

1. Hospitals, ambulatory surgical facilities, nursing homes, home-health agencies, ambulance providers, rescue groups, skilled nursing facilities, rehabilitation facilities, hospices, psychiatric facilities, and all other outpatient treatment and diagnostic facilities that are not a physician's office
2. Manufacturers of medical devices
3. Distributors of medical devices (at present, covered by a different regulation)

It is always useful to know whether the accident under investigation is common or rare, or whether there are precedents that could affect a judgment. Such background information is not always easy to locate. However, there are many sources of information on medical device accidents. MAUDE reports, institutional medical records, the incident report and depositions obtained from those present at the time of the accident contain valuable information.

Another useful source of FDA information is the 510(k) application for permission to sell a device that is substantially the same as one on that is the market. The IDE (Investigational Device Exemption) and the PMA (pre-market approval) are FDA documents that ensure that safety and efficacy considerations were met so that limited clinical trials of new medical devices are allowed. See Chapter 126 for a more detailed discussion of the FDA Center for Devices and Radiological Health.

Textbooks, Publications, and Organizations

The Handbook of Electrical Hazards and Accidents (Geddes, 1995) contains much information on the response of the body to the passage of low-and high-frequency current. A book by Pearce (1985) contains many examples of electrosurgical accidents. A chapter in a book by Fish (2000) describes many electrical accidents and includes many medical device accidents.

Several journals describe medical accidents; among these are *Medical Malpractice, Verdicts, Settlements and Experts*, and *The Forensic Examiner*. Reports of accidents also appear in *Health Devices* and *Health Devices Alerts* (see ECRI). *Health Devices Alerts* provides abstracts of selected technology assessments and contains a summary of reported medical device problems, hazards, recalls, and updates. The selections derive from extensive review of the medical, legal, and technical literature; reporting networks; and government sources worldwide. Most abstracts are taken from reports received within one month of the publication date of the issue.

SEAK, Inc. hosts many expert witness conferences that address medical malpractice and accidents. (See, e.g., Dyro, 2003b.)

Information on anesthesia-related accidents is available from the American Society of Anesthesiologists, which maintains a closed-claims database. A wide variety of accidents that occurred during anesthesia are described in it. In addition, the Wood Library–Museum of Anesthesiology also maintains a database of anesthesia accidents.

Published papers on accidents can be accessed through a library search of key words. The National Library of Medicine and the Web of Science are good sources.

Medical Device Standards

Before the FDA was granted authority to regulate medical devices in 1976, various professional societies had made recommendations for minimum performance of devices. In parallel with these activities, several standards-promulgating groups, notably the National Fire Protection Association (NFPA) and Underwriters Laboratories (UL), concerned themselves with the safety of medical devices. Now, there are standards for efficacy and safety for medical devices that have resulted from the activities of the FDA device classification panels. The American National Standards Institute (ANSI) serves as the national coordinating body for all standards-setting organizations. Organizations that publish medical device standards include the Association for the Advancement of Medical Instrumentation (AAMI), the American Society for Testing Materials (ASTM), and the Electronic Industries Association (EIA). The Canadian Standards Association (CSA) and the International Electrotechnical Commission (IEC) each promulgate medical device standards. The IEC has a wider range of performance standards than is required in the U.S., and when a U.S. standard is absent, the IEC standard is often cited. A wide variety of standards documents can be obtained from Global Engineering Documents and the Guide to Biomedical Standards.

Legal Documents

Two enormous databases cover the legal aspects of medical mishaps, as well as a wide variety of other subjects, including patents and patent infringement cases. The Lexis-Nexis database serves 60 countries. It has 7300 databases and adds 9.5 million documents each week. Both legal and nonlegal information is available. The West Publishing Company operates the Westlaw database and contains federal and state case law entries. Attorney editorial services can be provided, and a nominal charge is levied for each case, there being no subscription fees.

Medical Device Software Development

Richard C. Fries

Manager, Support Engineering, Datex-Ohmeda, Inc.
Madison, WI

Andre E. Bloesch

Datex-Ohmeda, Inc.
Madison, WI

Many kinds of medical devices are rapidly becoming software-intensive. Software controls their operation, collects and analyzes information to help make treatment decisions, and provides a way for users to interface with the medical device. In these devices, the software transforms a general purpose computer into a special-purpose medical device component. As in hardware design, specifying the software requirements, creating a sound software design and correctly implementing it are difficult intellectual challenges. Good software development is based on a combination of creativity and discipline. Creativity provides resolution to new technical hurdles and the challenges of new market and user needs. Discipline provides quality and reliability to the final product.

Software design and implementation is a multi-staged process in which system and software requirements are translated into a functional program that addresses each requirement. Software design begins with the work products of the Software Requirements Specification. The design itself is the system architecture, which addresses each of the requirements of the specification and any appropriate software standards or regulations. The design begins with the analysis of software-design alternatives and their trade-offs. The overall software architecture is then established, along with the design methodology to be used and the programming language to be implemented. A risk analysis is performed and then refined to ensure that malfunction of any software component will not cause harm to the patient, the user, or the system. Metrics are established to check for program effectiveness and reliability. The Requirements Traceability Matrix is reviewed to ensure that all requirements have been addressed. Peers review the software design for completeness.

The design continues with modularizing the software architecture, assigning specific functionality to each component and ensuring that internal and external interfaces are well defined. Coding style and techniques are chosen based on their proven value and the intended function and environment of the system. Peer reviews ensure the completeness and effectiveness of the design. The detailed design also establishes the basis for subsequent verification and validation activity. The use of automated tools throughout the development program is an effective method for streamlining the design and development process and assists in developing the necessary documentation.

The key to success in verification and validation is planning. Verification and validation planning encompasses the entire development life cycle, from requirements generation to product release. The initial planning of verification and validation is documented in a Software Verification and Validation Plan (SVVP). The SVVP describes the verification and validation life cycle, gives an overview of verification and validation, describes the verification and validation life cycle activities, defines the verification and validation documentation, and discusses the verification and validation administrative procedures. An excellent guideline for verification and validation planning can be found in IEEE Std 1012, with an explication of Std 1012 found in IEEE Std 1059.

Software Standards and Regulations

There are a myriad of software standards to assist the developer in designing and documenting a software program. IEEE standards cover documentation through all phases of design. Military standards describe the way that software is to be designed and developed for military use. There also are standards on software quality and reliability to assist developers in preparing a quality program. The international community has produced standards that primarily address software safety. In each case, the standard is a voluntary document that has been developed to provide guidelines for designing, developing, testing, and documenting a software program.

In the United States, the FDA is responsible for ensuring that the device utilizing the software, or the software as a device, is safe and effective for its intended use. The FDA has produced several drafts of reviewer guidelines, auditor guidelines, software policy, and good manufacturing practices (GMP) regulations addressing device and process software. In addition, guidelines for FDA reviewers have been prepared, as have training pro-

grams for inspectors and reviewers. The new version of the GMP regulation addresses software as part of the design phase.

The United States is ahead of other countries in establishing guidelines for medical software development. However, there is movement within several international organizations to develop regulations and guidelines for software and software-controlled devices. For example, ISO 9000-3 specifically addresses software development in addition to what is contained in ISO 9001. CSA addresses software issues in four standards covering new and previously developed software in critical and noncritical applications. IEC has a software-development document currently in development. They also have a risk analysis document (IEC 601-1-4).

Design Alternatives and Tradeoffs

The determination of the design and the allocation of requirements is a highly iterative process. Alternative designs are postulated that could, or are candidates to, satisfy the requirements. The determination of these designs is a fundamentally creative activity, a "cut and try" determination of what might work. The specific techniques used are numerous and call upon a broad range of skills. They include control theory, optimization, consideration of man-machine interface, use of modern control test equipment, queuing theory, communication and computer engineering, statistics, and other disciplines. These techniques are applied to factors such as performance, reliability, schedule, cost, maintainability, power consumption, weight, and life expectancy.

Some of the alternative designs will be quickly discarded, while others will require more careful analysis. The capabilities and quality of each design alternative is assessed using a set of design factors that are specific to each application and to the methods of representing the system design.

Certain design alternatives will be superior in some respects, while others will be superior in different respects. These alternatives are "traded off," one against the other, in terms of the factors that are important for the system being designed. The design ensues from a series of technology decisions, which are documented with architecture diagrams that combine aspects of data and control flow. As an iterative component of making technology decisions, the functionality expressed by the data flow and control flow diagrams from system requirements analysis is allocated to the various components of the system. Although the methods for selection of specific technology components are not a part of the methodology, the consequences of the decisions are documented in internal performance requirements and timing diagrams.

Finally, all factors are taken into account, including customer desires and political issues to establish the complete system design. The product of the system design is called an "architecture model." The architecture includes the components of the system, allocation of requirements, and topics such as maintenance, reliability, redundancy, and self-test.

Software Architecture

Software architecture is the high-level part of software design, the frame that holds the more detailed parts of the design. Typically, the architecture is described in a single document called the "architecture specification." The architecture must be a prerequisite to the detailed design, because the quality of the architecture determines the conceptual integrity of the system. This, in turn, determines the ultimate quality of the system.

A system architecture first needs an overview that describes the system in broad terms. It also should contain evidence that alternatives to the final organization have been

considered and the reasons why the organization used was chosen over the alternatives. The architecture should also contain:

- Definition of the major modules in a program. What each module does should be well defined, as well as the interface of each module
- Description of the major files, tables, and data structures to be used. It should describe alternatives that were considered and should justify the choices that were made
- Description of specific algorithms or reference to them
- Description of alternative algorithms that were considered and indicate the reasons why certain algorithms were chosen
- In an object-oriented system, specification of the major objects to be implemented. It should identify the responsibilities of each major object and ways in which the object interacts with other objects. It should include descriptions of the class hierarchies, of state transitions, and of object persistence. It also should describe other objects that were considered and should give reasons for preferring the chosen organization.
- Description of a strategy for handling changes clearly. It should show that possible enhancements have been considered and that the enhancements most likely are also the easiest to implement
- Estimation of the amount of memory used for nominal and extreme cases

Software architecture contemplates two important characteristics of a computer program: The hierarchical structure of procedural components (modules); and the structure of data. Software architecture is derived through a partitioning process that relates elements of a software solution to parts of a real-world problem implicitly defined during requirements analysis. The evolution of a software structure begins with a problem definition. The solution occurs when each part of the problem is solved by one or more software elements.

Choosing a Methodology

It seems there are about as many design methodologies as there are engineers to implement them. Typically, the methodology selection entails a prescription for the requirements analysis and design processes. Of the many popular methods, each has its own merit, based on the application to which the methods are applied. The tool set and methodology selection should run hand-in-hand. Tools should be procured to support established or tentative design methodology and implementation plans. In some cases, tools are purchased to support a methodology already in place. In other cases, an available tool set dictates the methodology. Ideally, the two are selected at the same time, following a thorough evaluation of need.

Selecting the right tool set and design methodology should not be based on a flashy advertisement or a suggestion from an authoritative methodology guru. It is important to understand the environment in which it will be employed and the product to which it will be applied. Among other criteria, the decision should be based on the size of the project (i.e., the number of requirements), the type of requirements (i.e., hard or soft real-time), the complexity of the end-product, the number of engineers, the experience and skill level of the engineers, the project schedules, the project budget, the reliability requirements, and the future enhancements to the product (i.e., maintenance concerns). Weight factors should be applied to the evaluation criteria. One way or another, whether the evaluation is conducted in a formal or informal way, involving one person or more, it should be done to ensure a proper fit for the organization and product.

Regardless of the approach used, the most important factor to be considered for the successful implementation of a design methodology is software-development-team buy-in. The software development team must possess the confidence that the approach is appropriate for the application and must be willing and "excited" to tackle the project. The implementation of a design methodology takes relentless discipline. Many projects have been unsuccessful as a result of lack of commitment and faith.

The two most popular formal approaches applied to the design of medical products are the Object Oriented Analysis/Design and, the more traditional, (top-down) Structured Analysis/Design. There are advantages and disadvantages to each. Either approach, if done in a disciplined and systematic manner along with the electrical system design, can provide for a safe and effective product.

Choosing a Language

Programming languages are the notational mechanisms that are used to implement software products. Features available in the implementation language exert a strong influence on the architectural structure and algorithmic details of the software. Choice of language also has been shown to have an influence on programmer productivity. Industry data have shown that programmers are more productive using a familiar language than an unfamiliar one. Programmers who work with high-level languages achieve better productivity than do those who work with lower-level languages. Developers who work with interpreted languages tend to be more productive than those who work with compiled languages. In languages that are available in both interpreted and compiled forms, programs can be productively developed in the interpreted form, and then released in the better-performing, compiled form.

Modern programming languages provide a variety of features to support development and maintenance of software products. These features include:

- Strong type checking
- Separate compilation
- Used-defined data types
- Data encapsulation
- Data abstraction.

The major issue in type checking is flexibility versus security. Strongly typed languages provide maximum security, while automatic type coercion provides maximum flexibility. The modern trend is to augment strong type checking with features that increase flexibility while maintaining the security of strong type checking.

Separate compilation allows retention of program modules in a library. The modules are linked into the software system, as appropriate, by the linking loader. The distinction between independent compilation and separate compilation is that type checking across compilation-unit interfaces is performed by a separate compilation facility, but not by an independent compilation facility. User-defined data types, in conjunction with strong type checking, allow the programmer to model and to segregate entities from the problem domain using a different data type for each type of problem entity. Data encapsulation defines composite data objects in terms of the operations that can be performed on them, and the details of data representation and data manipulation are suppressed by the mechanisms. Data encapsulation differs from abstract data types in that encapsulation provides only one instance of an entity.

Data abstraction provides a powerful mechanism for writing well-structured, easily modified programs. The internal details of data representation and data manipulation can be changed at will and, provided that the interfaces of the manipulation procedures remain the same, other components of the program will be unaffected by the change, except perhaps for changes in performance characteristics and capacity limits. Using a data-abstraction facility, data entities can be defined in terms of predefined types, user-defined types, and other data abstractions, thus permitting systematic development of hierarchical abstractions.

Software Risk Analysis

Software risk analysis techniques identify software hazards and safety-critical single- and multiple-failure sequences; determine software safety requirements; including timing requirements; and analyze and measure software for safety. While functional requirements often focus on what the system shall do, risk requirements must also include what the system shall not do, including means of eliminating and controlling system hazards and of limiting damage in case of a mishap. An important part of the risk requirements is the specification of the ways in which the software and the system can fail safely and extent the extent to which failure is tolerable.

Several techniques have been proposed and used in for conducting risk analysis, including:

- Software hazard analysis
- Software fault tree analysis
- Real time logic

Software hazard analysis, like hardware hazard analysis, is the process whereby hazards are identified and categorized with respect to criticality and probability. Potential hazards that must be considered include normal operating modes, maintenance modes, system failure or unusual incidents in the environment, and errors in human performance. Once hazards are identified, they are assigned a severity and probability. Severity involves a qualitative measure of the worst credible mishap that could result from the hazard. Probability refers to the frequency with which the hazard occurs. Once the probability and severity are determined, a control mode (that is, a means of reducing the probability and/or severity of the associated potential hazard) is established. Finally, a control method or methods will be selected, to achieve the associated control mode.

Real-time logic is a process whereby the system designer first specifies a model of the system in terms of events and actions. The event-action model describes the data-dependency and temporal ordering of the computational actions that must be taken in response to events in a real-time application. The model can be translated into Real Time Logic formulas. The formulas are transformed into predicates of Presburger arithmetic with uninterpreted integer functions. Decision procedures are then used to determine whether a given risk assertion is a theorem that is derivable from the system specification. If so, the system is safe with respect to the timing behavior denoted by that assertion, as long as the implementation satisfies the requirements specification. If the risk assertion is unsatisfiable with respect to the specification, then the system is inherently unsafe because successful implementation of the requirements will cause the risk assertion to be violated. Finally, if the negation of the risk assertion is satisfiable under certain conditions, then additional constraints must be imposed on the system to ensure its safety.

Software Metrics

Software must be subjected to measurement in order to achieve a true indication of quality and reliability. Quality attributes must be related to specific product requirements and must be quantifiable. These aims are accomplished through the use of metrics. Software-quality metrics are defined as quantitative measures of an attribute that describes the quality of a software product or process. Using metrics for improving software quality, performance, and productivity begins with a documented software development process that will be improved incrementally. Goals are established with respect to the desired extent of quality and productivity improvements over a specified time period. These goals are derived from, and are consistent with, the strategic goals for the business enterprise.

Metrics that are useful to the specific objectives of the program, that have been derived from the program requirements, and that support the evaluation of the software consistent with the specified requirements must be selected. To develop accurate estimates, a historical baseline must be established, consisting of data collected from previous software projects. The data collected should be reasonably accurate, collected from as many projects as possible, consistent, and representative of applications that are similar to work that is to be estimated. Once the data have been collected, metric computation is possible.

Metrics that can be used to measure periodic progress in achieving the improvement goals are then defined. The metric data collected can be used as indicators of development process problem areas, and improvement actions identified. These actions can be compared and analyzed with respect to the best return on the business's investment. The measurement data provide information for investing wisely in tools for quality and productivity improvement.

A feedback mechanism must be implemented so that the metrics data can provide guidance for identifying actions to improve the software development process. Continuous improvements to the software development process result in higher-quality products and increased development team productivity. The process-improvement actions must be managed and controlled so as to achieve dynamic process improvement over time.

Requirements Traceability

It is becoming increasingly apparent how important thorough requirements traceability is, during the design and development stages of a software product, especially in large projects with requirements that number in the thousands or tens of thousands. Regardless of the design and implementation methodology it is important to ensure that the design is meeting its requirements during all phases of design. To ensure that the product is designed and developed in accordance with its requirements throughout the development cycle, individual requirements should be assigned to design components. Each software requirement, as might appear in a software-requirements specification, for example, should be uniquely identifiable. Requirements that result from design decisions (i.e., implementation requirements) should be uniquely identified and tracked along with product functional requirements. This process not only ensures that all functional and safety features are built into the product as specified, but also drastically reduces the possibility of requirements "slipping through the cracks". Overlooked features can be much more expensive when they become design modifications at the tail end of development.

The Requirements Traceability Matrix (RTM) is generally a tabular format with requirement identifiers as rows, and design entities as column headings. Individual matrix cells are marked with file names or design-model identifiers to denote that a requirement is satisfied within a design entity. A Requirements Traceability Matrix ensures completeness and consistency with the software specification, which can be accomplished by forming a table that lists the requirements from the specification versus the way each is met in each phase of the software-development process.

Software Reviews

Timely and well-defined reviews are integral parts of all design processes. Each level of design should produce design-review deliverables. Software project development plans should include a list of the design phases, the expected deliverables for each phase, and a sound definition of the deliverables to be audited at each review.

Reviews of all design material have several benefits. First and foremost, authors are more compelled to elevate the quality of their work when they know that their work is being reviewed. Second, reviews often uncover design blind spots and alternative design approaches. Finally, the documentation generated by the reviews is used to acquire agency approvals for process and product.

Software reviews can take several different forms:

- Inspections, design, and code
- Code walk-throughs
- Code reading
- Dog-and-pony shows

An inspection is a specific kind of review that has been shown to be extremely effective in detecting defects, and to be relatively economical as compared to testing. Inspections differ from the usual reviews in several ways:

- Checklists focus the reviewer's attention on areas that have been problems in the past
- The emphasis is on defect detection, not correction
- Reviewers prepare for the inspection meeting beforehand and arrive with a list of the problems they have discovered
- Data are collected at each inspection and is fed into future inspections to improve them

The general experience with inspections has been that the combination of design and code inspections usually removes 60%–90% of the defects in a product. Inspections identify error-prone routines early, and reports indicate that they result in 30% fewer defects per 1000 lines of code than walkthroughs do. The inspection process is systematic because of its standard checklists and standard roles. It is also self-optimizing because it uses a formal feedback loop to improve the checklists and to monitor preparation and inspection rates.

A walkthrough usually involves two or more people discussing a design or code. It might be as informal as an impromptu bull session around a whiteboard; it might be as formal as a scheduled meeting with overhead transparencies and a formal report sent to management.

Following are some of the characteristics of a walkthrough:

- The walkthrough is usually hosted and moderated by the author of the design or code under review.
- The purpose of the walkthrough is to improve the technical quality of a program, rather than to assess it.
- All participants prepare for the walkthrough by reading design or code documents and by looking for areas of concern.

- The emphasis is on error detection, not correction.
- The walkthrough concept is flexible and can be adapted to the specific needs of the organization using it.

When used intelligently, a walkthrough can produce results that are similar to those of an inspection; i.e., it typically can find between 30% and 70% of the errors in a program. Walkthroughs have been shown to be marginally less effective than inspections, but under some circumstances they can be preferable.

Code reading is an alternative to inspections and walkthroughs. In code reading, source code is read for errors. Readers also comment on qualitative aspects of the code, such as its design, style, readability, maintainability, and efficiency. A code reading usually involves two or more people reading code independently and then meeting with the author of the code to discuss it. To prepare for a meeting, the author hands out source listings to the code readers. Two or more people read the code independently. When the reviewers have finished reading the code, the code-reading meeting is hosted by the author of the code and focuses on problems that the reviewers have discovered. Finally, the author of the code fixes the problems that the reviewers have identified.

"Dog-and-pony shows" are reviews in which a software product is demonstrated to a customer. The purpose of these reviews is to demonstrate to the customer that the project is viable, so they are management reviews rather than technical reviews. They should not be relied upon to improve the technical quality of a program. Technical improvement comes from inspections, walkthroughs, and code reading.

Performance Predictability and Design Simulation

The effort to predict the real-time performance of a system is a key activity of design that some software developers often overlook. During the integration phase, software designers often spend countless hours trying to fine-tune a system that has bottlenecks "designed in". Execution estimates for the system interfaces, response times for external devices, algorithm execution times, operating system context-switch time, and I/O device access times in the forefront of the design process provide essential input into software design specifications.

For single processor designs, mathematical modeling techniques such as Rate Monotonic Analysis (RMA) should be applied, to ensure that all required operations of that processing unit can be performed within the expected timeframes. System designers often fall into the trap of selecting processors before the software design has been considered, only to experience major disappointment and "finger pointing" when the product is released. It is imperative to a successful project that the processor selection comes after a processor-loading study is complete.

In a multiprocessor application, up-front system performance analysis is equally important. System anomalies can be very difficult to diagnose and resolve in multiprocessor systems with heavy interprocessor communications and functional expectations. Performance shortcomings that appear to be the fault of one processor are often the result of a landslide of smaller inadequacies from one or more of the other processors or subsystems. Person-years of integration phase defect resolution can be eliminated by front-end system design analysis and/or design simulation. Commercial tools are readily available to help perform network and multiprocessor communications analysis and execution simulation. Considering the pyramid of effort that is needed in software design, defect correction in the forefront of design yields enormous cost savings and increased reliability in the end.

Coding

For many years, the term "software development" was synonymous with coding. Today, for many software-development groups, coding is now one of the shortest phases of software development. In fact, in some cases, although very rare in world of real-time embedded software development, coding is actually done automatically from higher-level design (mspecs) documentation by automated tools called "code generators."

With or without automatic code generators, the effectiveness of the coding stage is dependent on the quality and completeness of the design documentation generated in the immediately preceding software development phase. The coding process should be a simple transition from the module specifications, and, in particular, the pseudocode. Complete mspecs and properly developed pseudocode leave little to interpretation for the coding phase, thus reducing the chance of error.

The importance of coding style (how it looks) is not as great as the rules that facilitate comprehension of the logical flow (how it relates). In the same light, in-line code documentation (comments) should most often address "why" rather than "how" functionality is implemented. These two focuses help the code reader to understand the context in which a given segment of code is used. With precious few exceptions (e.g., high-performance-device drivers) quality source code should be recognized by its readability, and not by its raw size (i.e., the number of lines) or its ability to take advantage of processor features.

Design Support Tools

Software development is very labor-intensive and, is therefore, prone to human error. In recent years, commercial software-development support packages have become increasingly more powerful, less expensive, and more available to reduce the time spent doing things that computers do. Although selection of the right tools can mean up-front dedication of some of the most talented resources in a development team, it also can bring about significant long-term increase in group productivity.

Good software-development houses have taken advantage of CASE tools that reduce the time spent generating clear and thorough design documentation. The advantages of automated software-design packages are many. Formal documentation can be used as proof of product development procedure conformance for agency approvals. Clear and up-to-date design documents facilitate improved communications between engineers, thus leading to more effective and reliable designs. Standard documentation formats reduce learning curves that are associated with unique design depictions among software designers, thus leading to better and more timely design formulation. Total software life cycle costs are reduced (especially during maintenance) due to reduced ramp-up time and more efficient and reliable modifications. Finally, electronic forms of documentation can be easily backed up and stored off-site, thus eliminating a crisis in the event of an environmental disaster. In summary, the adaptation of CASE tools has an associated up-front cost that is recovered by significant improvements in software quality and development-time predictability.

Design as the Basis for Verification and Validation

Verification is the process of ensuring that all products of a given development phase satisfy given expectations. Prior to proceeding to the next-lower level or phase of design, the product (or outputs) of the current phase should be verified against the inputs of the previous stage. A design process cannot be a “good” process without the verification process ingrained—they naturally go hand-in-hand.

Software project management plans (or software quality assurance plans) should specify all design reviews. Each level of design will generate documentation to be reviewed or deliverables to verify against the demands of the previous stage. For each type of review, the software-management plans should describe the purpose, materials required, scheduling rules, scope of review, attendance expectations, review responsibilities, what the minutes should look like, follow-up activities, and any other requirements that relate to company expectations.

At the code level, code reviews should ensure that the functionality implemented within a routine satisfies all expectations documented in the “mspecs.” Code also should be inspected, to satisfy all coding rules.

The output of good software designs also includes implementation requirements. At a minimum, implementation requirements include the rules and expectations placed on the designers to ensure design uniformity as well as constraints, controls, and expectations placed on designs to ensure that upper-level requirements are met. General examples of implementation requirements might include rules for accessing I/O ports, timing requirements for memory accesses, semaphore arbitration, inter-task communication schemes, memory-addressing assignments, and sensor- or device-control rules. The software-verification and -validation process must address implementation requirements as well as the upper-level software requirements to ensure that the product works as it was designed to.

Verification and Validation Life Cycle

An SVVP lays out the framework from which the verification and validation activities proceed. IEEE 1012-1986 is very detailed about development life cycle and the verifica-

tion and validation products that are generated at each phase. Specifically, the standard calls out the following phases:

- Concept phase
- Requirements phase
- Design phase
- Implementation phase
- Test phase
- Installation phase
- Operation and maintenance phase

In industry, it is more typical for software verification and validation to follow a simpler model, as shown in the Figure 85-1.

This model is simpler in that it focuses verification and validation activities on the software that is generated, rather than on output of every phase of development. Another document, called the Software Quality Assurance Plan (SQAP), is used to cover other verification and validation aspects of product development, such as software requirements reviews, hazard and risk analysis, and design reviews.

Using the model as shown in Figure 85-1, software validation testing covers validation of the software product by testing against the requirements generated in the requirements-generation phase. Software validation is analogous to black box testing. Integration testing covers verification of features defined from the requirements-generation phase, the concept/high-level design phase, and the feature-interface design phase. Integration testing tests the collection of software modules, where the software modules are joined together to provide a product feature or higher level of functionality. Finally, unit testing covers verification at the lowest level, which includes the feature interface design phase and the low-level design phase. Unit testing typically covers the verification of smaller collections of software modules.

Verification and Validation Overview

The verification and validation overview describes many of the project management details that must be addressed in order to perform the verification and validation functions. They include the verification and validation organization; a schedule; resources; responsibilities; and any special tools, techniques, and methodologies.

The organization describes who is responsible for carrying out the various verification and validation efforts. In practice, this section is used to describe who will be responsible for maintaining the laboratory, who will manage the validation testing, who will manage verification testing, and who will be responsible for anomaly resolution.

Verification and validation scheduling is very important for planning activities in order to support the overall product schedule. Often, a higher-level schedule is entered into the software verification and validation plan, and a detailed schedule is maintained apart from the software verification and validation plan. This is generally due to different software applications for generating a schedule and for generating documentation.

The resources section describes all of the equipment, software, and hardware that are required, to perform verification and validation activities. A subsection also should be included on the validation of using any software tools, where the software tool is used as part of the verification and validation process. Per the FDA’s regulations (FDA, Quality

Typical Software Development Model

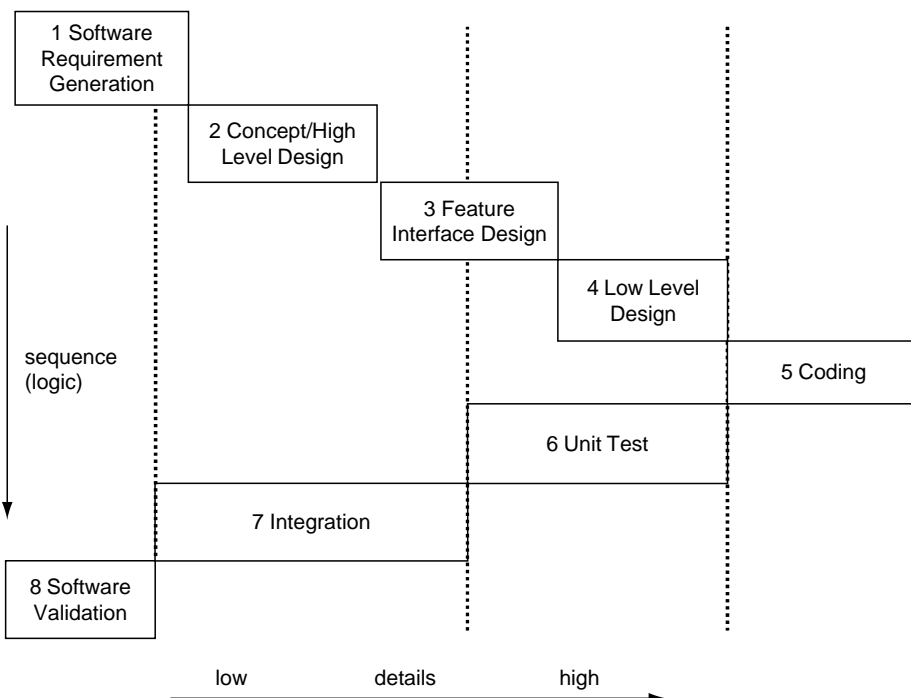

Figure 85-1 Typical software development model.

System Regulation, 21 CFR Part 820, June 1, 1997), any device that is used in a company's quality system must be validated. A test fixture or a customized software application clearly falls under this definition. Thus, it is necessary to validate the software tool.

Verification and Validation Life Cycle Activities

In the SVVP, this section typically includes the criteria, inputs/outputs, reviews, testing approach, and training for each verification and validation phase. The criteria describes the goal that each phase is defined to achieve. The inputs/outputs phase defines what things are needed as inputs into the phase and what the product of each phase are.

It is also helpful to add a subsection on the general functionality that will be tested. The IEEE standard does not call this out. However, adding this subsection is helpful to reviewers of the software verification and validation plan. It provides information on the functionality that is scheduled for testing.

Verification and Validation Documentation

Each verification and validation phase has its activities and documentation that is associated with it. For unit, integration, and software validation test phases, typically there are test plans, test procedures, and test results and reports.

For software validation, there usually are some additional documents. The Software validation group typically has a requirements-to-test cross-reference. The cross reference ensures that all the requirements defined in the SRS are covered in some test. It is also helpful in the cross-reference document to include a test-to-requirement cross-reference. This backward reference helps to ensure that a requirement has adequate coverage. The software validation group also generates a procedure-response document, which serves as a means to close out any issues or comments that occurred on during an official validation pass. Finally, the software validation group has been responsible for writing a final report called the software verification and validation report (SVVR), which summarizes the activities from all of the previous verification and validation phases.

Verification and Validation Administrative Procedures

The verification and validation administrative procedures section provides additional guidance on ways that the verification and validation will be conducted. IEEE Std 1012-1986 defines this section as including anomaly reporting/resolution, task iteration policy, deviation policy, control procedures, and standards/practices/conventions.

It is also useful to include section metrics. IEEE Std 730.1-1989, IEEE Standard for Software Quality Assurance Plans, includes metrics as part of a SQAP. The following subsections describe in more detail anomaly reporting, metrics collection, and reporting, and they provide some additional topics that are important to verification and validation.

Anomaly Reporting and Resolution

One result of verification and validation is the generation of anomalies found during testing. A process for reporting anomalies must be in place to record anomalies. Some institutions have used a lab notebook to document anomalies. More frequently, a PC-based database program is used to log and to store anomalies electronically.

In addition, a process must be in place for resolution of anomalies found against the product software. It can be a committee of people who are responsible for the product or simply the software test coordinator who is working with the primary software developer. The responsible parties determine the risk of each anomaly.

Validation Metrics

There are several aspects of verification and validation in which it is helpful to generate metrics. The first and most obvious one is anomaly metrics. An example of anomaly metric tracking is shown in Figure 85-2. This chart shows the tracking of open severitized anomalies as a function of time.

The second aspect of test metrics is those involving test development. These metrics are used to monitor the test development process and to monitor overall test parameters for all projects. Monitoring the test development process ensures that the test development is proceeding according to schedule. An example is shown in Figure 85-3.

Configuration Management

Just as it is important to maintain a configuration for product development code, it is equally important to practice configuration management on test protocols. Configuration of test materials includes:

- Script libraries
- Test scripts
- Manual protocol
- Test results

Figure 85-2 Metric chart showing open anomalies sorted by severity

Figure 85-3 Monitoring the test-development process.

- Test plans and procedures
- Test system design

Protocol Templates

To make the development of tests more uniform and efficient, it is advisable to have templates for the test protocol. If test scripts are written, then a set of development guidelines is suggested.

Test Execution

This section discusses approaches that are used when executing manual protocol and automated scripts.

Process Improvement

No test process is perfect. There are always ways to improve the test-development process to do things more efficiently. Thus, some time should be set aside for review of the current processes that are in place. If the test team is large enough, a process team can be created to address processes and process changes in the test group. Discussions should occur among test team members to determine those processes that worked well and those that did not.

Test Development

Requirements Analysis and Allocating Requirements

Today, it is assumed that a software requirements specification (SRS) is written. The SRS describes the behavior and functionality of the software in the medical device. It should obtain its inputs from the following sources:

- Derivation of the product specification
- Control procedures from the risk and hazard analyses
- Regulatory requirements, such as safety-relevant computing

A large part of the verification and validation effort will concentrate on proving that these software requirements are fulfilled. Therefore, the requirements in the software requirements specification must be enumerated to permit proper allocation to the different test phases and the specific tests.

The initial analysis of the software requirements specification involves determining where to test a particular requirement. Where a requirement is tested is often based on the capabilities of the test fixture used in validation. Usually, most requirements can be tested at the validation level. The balance of the requirements is then tested during integration or unit testing. In general, a requirement that has external stimulus (to the central processing unit (CPU)) and the ability to monitor externally are done at the validation level. Exceptions to this are conditions that might require very specific timing, and that timing is calculated internally to the CPU.

Requirements that are tested during integration or unit testing are typically those that cannot be tested sufficiently during validation testing. Testing a “software watchdog error” requirement is good example of a requirement tested during integration or unit testing. In this case, the software is monitoring itself, and there is no external means to cause the fault.

The second step of the requirements analysis phase is to determine the best way to group the requirements into tests. One relatively straightforward approach to doing this is to create tests based on sections in the software requirements specification. Typically, a section in an SRS will describe a feature almost fully. By following the software requirements specification format, the tests then are developed by feature, which is a logical approach. Of course, there will be requirements in the software requirements specification where this approach will not apply. In such cases, further analysis must be done to assess whether additional tests should be created, or whether one of these “special” requirements can be allocated into those tests that follow the software requirements specification.

As mentioned at the beginning of this section, control procedures from the risk and hazard analysis should be written into the software requirements specification. If this is done, then those risk/hazard requirements simply will be analyzed and allocated to tests just like all other requirements.

Storing the allocation matrix is a final aspect of requirements allocation to test. It is simple enough to keep the matrix in a spreadsheet or an electronic document. However, it can also be stored in a database. The advantage of storing it in a database is that a user can track test development and also can generate numerous reports.

Testing Phases and Approaches

Unit Testing

Unit testing is performed on a smallest amount of code. What comprises a “unit” is often the subject of lengthy discussion and debate. No matter how a unit is defined, the intent of unit testing is to ensure that the lowest-level software modules are tested.

There are several approaches to unit testing, such as branch path analysis or module interface testing. In branch-path analysis, the developer uses a development tool to step through each path within a unit. In module-interface testing, the developer tests the unit from a “black box” perspective. Thus, the unit is only tested by varying the inputs into the software unit.

The type of unit testing that will be required will depend on many factors. In medical devices, the detailed branch path analysis testing is usually done against software units that are considered to be critical to the safety of the patient or the user. Other, lesser critical software units can be justifiably tested using the less thorough module interface testing.

Integration Testing

Integration testing has several definitions. The definition covers the integration of two or more software units together. A broader definition covers the integration of physical subsystems (each with its own embedded software) to ensure that they work together.

Either type of integration testing brings separately developed entities together to ensure that they work together. The type of testing that is usually performed at these levels involves writing protocols to exercise the interface.

Validation Testing

Validation testing is the process of proving that the product meets the product specification. It also can mean going the extra step and trying to ensure that the product does not do what it is not supposed to do. Thus, several approaches to testing are employed to exercise the software product. These approaches are discussed below.

Requirements-Based Testing

Requirements-based testing is the primary approach that is used to validate software. Essentially, the requirements from the software requirements specification are analyzed and allocated to specific tests. Different approaches to testing, such as threshold testing or boundary testing, are used in developing these tests. The test steps are the sequential actions that must be taken to prove that the requirement has been met.

Threshold Testing

Threshold testing is the process of proving that an event will occur when a specified parameter exceeds a certain value. An alarm, such as a low-battery alarm, is a good example of this on a medical device. If the device is running on a battery, and the voltage level in the battery falls below a threshold level, then an alarm is enunciated. In these types of tests, a tolerance band is placed around the threshold level. The tolerance is determined by the requirements in the software requirements specification and also can be influenced by the accuracy of the test system. The test is then designed to vary the battery voltage to cross through the threshold and to see that the alarm is tripped within the tolerance band. Once the alarm has been tripped, the next part of the threshold test is to vary the parameter (in this case, the battery voltage) in the reverse direction to ensure that the alarm no longer enunciates.

Boundary Testing

Boundary testing is the exercise of testing a parameter at its limits, and of trying to exceed those limits. A measured value of O_2 that is defined as not to exceed 110% would be a good example of this. (An O_2 reading can exceed 100% if the O_2 sensor is out of calibration or calibrated incorrectly.) The test then would be designed to prove that 110% O_2 could be displayed. Additionally, the test then would see how the device would react if the measured O_2 value were to exceed 110%.

Stress Testing

Stress testing is the process of subjecting the unit to a bombardment of random inputs—often keypad presses or knob turns—to try to cause a software failure. This can be done manually or with an automated test system.

Manual stress testing and automated stress testing each have their own advantages. The advantage of manual stress testing is that the tester can test a certain aspect of the device can and observe anomalous behavior in other areas of the device. The advantage of automated stress testing is that the test system can provide inputs into the device much more quickly than a human tester can.

Volume Testing

Volume testing is the process of exercising the unit for an extended period of time. In our medical applications, we have found that running a volume test for a 72-hour period can uncover problems not found elsewhere.

Volume testing is almost always done with an automated test system. Volume testing does not necessarily use random fast, slam-bang key presses like stress testing does. Volume testing uses a logical approach to testing all of the paths in a software program. Once the device is in a certain state, probabilistic algorithms like Probability Density Function (PDF) are used in determining the next state.

Scenario Testing

Scenario testing is the act of writing a test that emulates the actual use of the software from the user’s perspective. For example, in anesthesia machines, a test could be written to cover a clinical situation. Scenario testing is helpful because it can uncover problems in the system, or it can detect flaws in the overall use of the product.

System Testing

System testing occurs to validate the entire medical device, not just the software that is embedded in the device. Depending on the way a test station is instrumented for software testing, there can be significant overlap between software and system testing. For

example, software embedded in a ventilator usually requires other mechanical-electrical subsystems in order to function. It is difficult to write sophisticated simulations to trick the ventilator software into thinking that all of the other subsystems of the ventilator are present. Therefore, a software test system might resemble a complete-system. It is up to the responsible parties to ensure that the degree of overlap is made known. More importantly, it is vital that everything is tested at some point in the product development.

Test Execution and Reporting

Test Plan

For software validation, a test plan is written prior to executing a test pass. The format follows that defined in ANSI/IEEE Std 1012. The key aspects of the test plan are the description of the software changes, and the tests that will be run to prove that those software changes are implemented correctly. The test plan is written whenever a full validation or a regression test is run.

Test-Configuration Form

Because it is very important to be able to repeat a test, it is necessary to document the configuration of the equipment that is used to run a test against. This documentation is written on a test configuration form. The contents of these forms can vary. However, the primary fields are date, item, and item serial number, and there is a place for the test engineer to sign his name. The test configuration form becomes part of the test-documentation suite.

Executing Manual Protocol

Executing manual protocol for a formal test involves printing out the test procedures and going through the steps in the procedures. Because these printouts are a part of the official documentation, the test engineer must sign and date the documents. If the tester finds problems during the test, he will document the issue on the test procedures.

It is important that the handwritten notes on the paper procedures be addressed. The notes on the procedures could be problems found or procedure deviations. All of these markings must have closure. This closure is formally documented in the procedures response document. The procedures response document is covered later in this chapter.

Executing Automated Protocol

Typically, executing automated protocol amounts to setting up a batch job to submit a series of tests to be run. A test engineer fills out a test configuration form to have a piece of paper to start off the test. The batch job is then run overnight, and the results are analyzed the following day.

Experience has shown that a test in the batch occasionally can fail. This failure usually has been attributable either to timing issues or to the target-device feature having changed but the test not having changed. When this happens, it is usually a practical matter simply to correct the test script and to rerun it. However, in instances where correcting the test script would consume a large amount of time, it is sometimes more efficient to run that test manually to complete the test pass.

Test Results

Once test results have been generated, they must be analyzed. The results from the automated tests are reviewed by running searches for keywords that indicate whether the test had problems. Additional analysis is performed by reviewing samples of the automated test results. This ensures that the tests executed as expected. Other analysis might need to occur, such as when a large amount of data are generated during the test, after which data reduction and analysis must be performed to assess correctness.

Test results must be managed along with the other test documentation. The results from the manual test procedures must be included with the other paper documentation and stored in the formalized location. The electronic results files also must be put under configuration control. This is done with a configuration-management tool or a process of backing up the files to controlled media.

Test Reports

Software Validation Test Report

The key items in this report are a summary of what was tested, how it was tested, any problems that were encountered, and a recommendation for release.

Requirements to Test Cross Reference

This document covers the ways in which the requirements were allocated to tests.

Procedures Response Document

As mentioned earlier, all handwritten marks on the manual test procedures must be reviewed and provided a closure. The results of this closure are documented in the procedures response document. Typically, each mark-up in a test procedure is a software problem, a procedure error, a procedure deviation, or a comment.

Comparative Evaluations of Medical Devices

James P. Keller

Director, Health Devices Group, ECRI
Plymouth Meeting, PA

Evaluating medical device technology is a complex process. Many factors contribute to its complexity, ranging from the wide variety of devices purchased and used in hospitals, to the various settings and applications where devices are used, to the many different types of users of the equipment. Many hospitals do not have a good process in place to address these complexities effectively or to evaluate their choices for medical technology. They subsequently make inappropriate, and sometimes unsafe, equipment procurement choices. The purpose of this chapter is to present a process that health care organizations can use to effectively evaluate medical technology. Many of the steps in this process are modeled after a 30-year-old, comparative brand-name evaluation program and processes used by ECRI, a research institute in Plymouth Meeting, Pennsylvania, to advise hospitals on medical device selection. Examples from ECRI's evaluation program will be used throughout this chapter.

Complexities of Hospital Purchase of Medical Equipment

Hospitals buy a large number of medical devices. \$155.5 billion was spent on medical devices worldwide, and \$66.5 billion was spent in the United States in 1999 (MHMG, 2000). The types of devices include capital equipment, computer-based systems, equipment integrated with computer-based systems, drug/device combinations, disposable/reusable products, and supplies. Most applications of the devices are for use within the hospital. However, many hospitals also acquire equipment and supplies for distribution by a durable medical equipment (DME) provider; for placement directly in a home setting by a hospital (e.g., without using the DME as a "middle man"); for research or a combination of research and clinical use; and for use in clinics, doctors' offices, nursing homes, patient-transport vehicles, same-day surgery facilities, and other settings. Depending on the setting, the hospital will have one user to a wide range of users for any given type of equipment. In most cases, the users of the equipment are health care professionals with some level of degree- or certificate-based training. However, many devices are used by untrained individuals and even by patients.

There are often several different types of devices that can be used for the same, or some of the same, types of applications. Hospitals typically have many vendors to choose from when selecting a class of medical equipment to purchase. Often, one manufacturer will offer several choices of equipment within the same device class, or several different configurations of the same device. Many hospitals rely on vendor information and specifications to make their purchasing decisions. However, vendor specifications are not presented in a standardized format from vendor to vendor. Specifications, product descriptions, and general product information (e.g., summaries of clinical studies) are also presented in the most positive light for each manufacturer. Clinical literature about the utility of products also might be biased (e.g., funded by manufacturers of the products being evaluated), incomplete, or of poor quality, and typically it is not comparative. This all results in a confusing, and often misleading, equipment purchasing data set for the hospital.

Medical equipment purchasing is rarely centrally controlled within an institution. Purchasing typically takes place independently in many departments throughout the same institution. In many cases, the different departments are purchasing equipment for the same or similar purposes. This results in a wide range of criteria and purchasing practices within the same institution, often with significantly different standards of care. When one hospital is part of a larger health care system, the number of variables in system-wide purchasing can become even more overwhelming.

Hospitals that participate in, or that are members of, group purchasing organizations (GPO) theoretically avoid some of the complexities described above. GPOs typically take advantage of the economies of scale provided by their membership, to negotiate substantial group-rate-type discounts for a large list of devices. GPO member hospitals that buy devices from the GPO lists will receive the negotiated pricing. The GPOs will list one-to-several choices for members within each device category on the list. However, GPO member hospitals usually have not had a direct say in selection of the GPO-selected products. These products have not been selected with the unique needs of each GPO member in mind. In fact, they might not have been selected for their clinical utility, effectiveness,

safety, or cost-effectiveness. The GPO's selection criteria sometimes can be solely based on the lowest negotiated price. Although the GPO member is not typically locked into only buying the products on the GPO contract list, it is in its best interest to strongly consider the discounted prices that are available. In fact, some GPO contracts are based on the GPO member committing to purchasing a certain number of devices from the GPO list in order to obtain the negotiated prices. However, similar or better bargains might be available elsewhere, and in order to be thorough, hospitals need to investigate whether the GPO-listed devices actually meet their specific needs.

The regulatory status of devices can impact their purchase. Most devices used for clinical applications are clearly labeled as medical devices according to FDA definitions. However, some devices, such as clinical information systems, do not have a formal regulatory status or others are in the process of becoming approved or cleared for sale within certain jurisdictions. Hospitals that are interested in purchasing this type of equipment have an additional set of factors to consider before purchasing, relating to liability, insurance coverage, government reimbursement, competence of users, patient consent, and other issues.

The complexities discussed above are but a few of those that hospitals are confronted with when purchasing their wide range of medical devices. The best way to address these complexities is for hospitals to have a process in place to objectively evaluate its equipment needs and the true value of, and need for, the equipment that the institution is considering. This process will be discussed below and will be modeled, in large part, after a 30-year-old comparative brand-name evaluation program and processes used by ECRI to advise hospitals on medical device selection.

Identifying Equipment Needs

Medical devices are, in theory, purchased to meet one or more specific needs for the health care facility. Before any type of device evaluation takes place, however, those needs must be clearly defined. The need could be as simple as a measuring a patient's blood pressure. On the surface, the solution to the problem is to buy enough sphygmomanometers and stethoscopes to meet the needs of the clinicians who will be taking the measurements. However, "taking blood pressure measurements" is a general criterion. The hospital's true need, at least in some clinical departments, might be to record blood pressure readings automatically; to display the data in a way that can warn clinicians when blood pressure reaches dangerous levels; to store the readings in some form of database for trending of blood pressure fluctuations; and to integrate the blood pressure data with other clinical parameters to manage patient care more effectively. Handheld sphygmomanometers and stethoscopes clearly cannot meet these needs.

As with the blood pressure measurement example, most equipment purchase decisions are not as simple as the number and brand of device to buy. Each equipment purchase consideration must answer a series of questions before the purchasing process gets to the point of considering the number and brand to purchase. The first question to ask is whether you need equipment for an application. Sometimes, a better choice for an application might be drug therapy, rather than a device solution. If a device solution is appropriate, the next question concerns the type of equipment needed. Equipment evaluators should keep in mind that there might be several types of equipment choices, such as lasers, electrosurgical units, and harmonic scalpels for surgical dissection and coagulation. Each alternative must be considered with the specific needs of the institution in mind.

Equipment evaluators also should determine the clinical specialties that would need the equipment or that have similar needs. For example, orthopedic surgery might request a certain type of laser for dissecting tissue during joint surgery. However, the laser might not be used often enough merely by orthopedic surgeons, to justify such a costly acquisition; lasers for orthopedic surgery typically cost at least \$100,000. However, if it is determined that other surgical specialties will benefit from use of the laser as well, the acquisition could be justified.

Determining true clinical need is a critical step in the evaluation process. Unfortunately, many hospitals do not carefully consider this issue and have paid the high price of buying medical devices that are not really needed; the devices become expensive dust

collectors. In some cases, the equipment is utilized, but not often enough for staff to become proficient with its use. Each time the device is used, the clinical staff must relearn how to use it. When this happens, the cost of poor purchase decisions also becomes a safety concern. Patients and staff are at risk of being injured by medical devices that operators do not know how to use proficiently. ECRI has operated a medical device problem-reporting and investigation program for over 30 years. It has investigated many cases of serious patient or staff injury because use of medical devices that clinical staff did not fully understand how to use.

Careful research is required, to determine the true clinical need for medical devices. It should include interviews with staff who will be using or affected by the equipment; review of relevant clinical and technical literature on the benefits and drawbacks of the technology; review of the hospital's past history with similar equipment; surveys of other organizations' experience with the equipment being considered; discussions with manufacturers; review of manufacturer literature; and consultation with outside experts. In some cases, there will be overwhelming evidence that a certain type of technology is a standard of care and totally appropriate for the application(s) being considered. However, with new and emerging technologies, the information gathered must be examined critically for bias and quality of data. ECRI has observed many examples of new and emerging technologies being prematurely implemented because of over-reliance on poor-quality clinical data or overly vigorous promotion of the technology by proponents who will receive financial gains from its success.

Establishing Basic Selection Criteria

Once it has been determined that a certain class of equipment is needed by the hospital, the actual device-evaluation process can begin. The first step is to determine the features needed from the device. As mentioned above, there are often a wide variety of devices offered within one device class. Many of the features that are available for the different models are absolutely necessary for the devices to serve their main purpose. However, as with a car, many devices have features that might offer little more than cosmetic benefits that come at a high cost, the often-termed "bells and whistles." Other features might be clinically useful, but they are not needed for the specific application being considered. Conversely, some devices lack a key feature in order to work as designed. One of the first steps of a device evaluation is to identify the "must have" features for the devices being considered for purchase. Once these features have been identified, the universe of devices available for purchase can be narrowed down to a manageable number.

ECRI's brand-name comparative evaluation program uses a rating system that is based on an essential-features analysis. The rating system includes the rating categories of "preferred," "acceptable," "not recommended," and "unacceptable." Devices rated "unacceptable" have one or more features that prevent them from performing their intended purposes; create an unacceptable risk; or are prohibitively expensive. For example, infusion pumps that do not have automated protection from free-flow delivery of medications and other intravenous fluids can deliver a fatal overdose. ECRI rates infusion pumps that lack this feature as "unacceptable" and recommends that hospitals remove these devices from their purchase-consideration list. In fact, ECRI recommends that these devices be removed from use and replaced with the safer, free-flow protected devices. Other device features that have resulted in "unacceptable" ratings by ECRI have included needle-stick-prevention devices that lacked automated needle-stick protection (ECRI, 1999) and thoracic aspirators that lacked sufficient specified volumetric airflow to overcome large air leaks in the thoracic cavity and thus provide poor suction (ECRI, 1998a). In each example, the devices were not able to perform their intended purposes, at least according to ECRI's expectations, and they were unsafe.

The essential-features analysis from the ECRI evaluation examples cover generic problems or characteristics that would apply to any institution's situation. However, some issues will come up in a hospital's device selection that will be unique to its circumstances or at least a small sampling of similar hospitals. Part of the essential-features analysis is to identify the features that the devices under consideration must have, or should not have, in order to meet the hospital's unique needs. For example, if the hospital is operating under a specific software platform, with which a medical device based computer system is not compatible, the medical device should be ruled out of the hospital's purchase consideration unless the hospital is in the process of also upgrading the software platform to a compatible system. In another example, many hospitals are installing picture archiving and communications systems (PACS), systems used for archiving and viewing radiographic images. In order for these systems to work, they must be compatible with the radiographic imaging devices in the hospital (i.e., the PACS should be able to receive and read data from the imaging devices). If a significant number of devices in the institution are not compatible with the PACS, then the PACS will not be appropriate for consideration. In the PACS example, an extensive analysis, typically based on each system's level of compliance with the American College of Radiology (ACR) and the National Electrical Manufacturers Association (NEMA) Digital Imaging and Communications in Medicine (DICOM) standard, might be required in order to determine compatibility.

Detailed Comparative Evaluation Criteria

After narrowing down the device-selection options using an essential features analysis, the real comparative nature of the evaluation process can begin. This process involves comparing the devices or systems being considered in a variety of general categories. Within each category, specific criteria must be established in order to effectively compare the systems to one another. The general categories include overall performance and safety, ease of use and other human factors issues, quality of construction, service and support, and cost. Depending on the type of device or system being evaluated, one category might need to receive more attention than others in the evaluation process. Another factor that determines the category that receives a higher level of attention will be the setting for the device under consideration. Devices intended for home use, especially those used and operated by patients, will have significant ease-of-use concerns. Devices

intended for transport use, especially in helicopters, should receive a greater emphasis on quality-of-construction factors, such as the ability to withstand shock and vibration.

In order to conduct a thorough evaluation, a comprehensive set of criteria must be established for each device being evaluated in each of the general categories mentioned above. This can be a daunting task for any hospital or other health care institution, especially considering the large number and variety of medical devices purchased every year. However, despite the confusing set of device-selection data with which hospitals are confronted, resources do exist to make this process much more manageable. One of the most well-known and respected resources is the Health Devices Evaluation program operated by ECRI, a nonprofit corporation that engages in the independent evaluation of technology. For over 30 years, ECRI has been conducting evaluations comparative to those of a similar institution, Consumers Union, publisher of *Consumer Reports*. ECRI has established rigorous conflict-of-interest rules and evaluation methods that support its unequalled reputation as a totally objective and comprehensive medical technology information source. Hospitals routinely refer to ECRI's many comparative device evaluations for guidance on establishing their own evaluation criteria, or the ECRI criteria are fully adopted into the hospital's process.

Criteria for ECRI's comparative evaluations are developed through rigorous review of related clinical and technical literature, standards, and previous ECRI evaluations, and from ECRI's experience in working with and investigating problems involving the evaluated technology. ECRI technical staff members also spend many hours interviewing experts on, and users of, the technology and observing the technology in clinical use. Manufacturers of the evaluated products are invited to ECRI's laboratories to demonstrate their products and for questioning by ECRI technical staff. Through this process, important performance characteristics are identified, user problems are noted, and other evaluation-related factors are established, from which the details of the criteria are developed. Examples of device areas where evaluation criteria are established include allowable turning rotation on control knobs, alarm volume thresholds on anesthesia machines, flow control accuracy on critical care ventilators, radiation exposure dose limits on CT scanners, puncture resistance for surgical gloves, and level of acceptable display-screen clutter on physiologic monitors.

The ECRI criteria are packaged in a well-organized document and critically reviewed by ECRI technical staff, outside experts, users, and manufacturers whose products are being evaluated. This results in a comprehensive, but practical, set of expectations for the evaluated device or system. Hospitals must examine each of ECRI's criteria to verify that they apply to their unique situation. In most cases, the criteria will be completely applicable. Where a criterion does not apply or has not been established by ECRI, evaluations of similar technology by ECRI can be used to develop new, or to revise existing, criteria. The hospital conducting the evaluation can also use ECRI's process of reviewing relevant clinical and technical literature and standards, and consultations with experts (including ECRI staff) and users to develop the criteria.

Critical Evaluation Criteria

Because of the wide range of devices used in hospitals and other health care settings, it is impossible in the context of this chapter to describe critical-evaluation criteria for all of these devices. However, a number of examples based on recent ECRI evaluations and the experience of the author are presented below. Examples are provided for each of the general categories mentioned above.

Performance and Safety

Arthroscopic irrigation and distension systems are designed to distend a joint cavity with fluid to provide an orthopedic surgeon with a workable operating space within the joint during arthroscopic surgery. High pressures from the arthroscopic irrigation and distension systems are known to cause extravasation of the distension fluid into the tissue surrounding the joint cavity. At a minimum, extravasation can cause irritation and delayed healing in and around the surgically treated joint. More serious complications include nerve palsy, arterial compression, and even cardiac arrest. Clinical studies have shown that joint pressures of as low as 180 mm Hg can cause extravasation. To minimize the risk of extravasation, arthroscopic irrigation and distension, systems should have a limit so that they cannot deliver fluid in the joint at pressures higher than 180 mm Hg and joint pressure should be monitored by the arthroscopic irrigation and distension systems so that users can be alerted, should pressure levels reach the 180 mm Hg limit (ECRI, 1998b).

Ease of Use and Other Human Factors Issues

Blood glucose monitors are used by diabetic patients and clinicians to monitor and to help control a patient's blood glucose level. Most of these devices are used by patients outside of the hospital setting. Many of these patients are elderly, with limited manual dexterity and impaired vision. Blood glucose monitors have a reading port into which patients place a small calibrated test strip, onto which they have applied blood, for analysis. In order to accommodate users with limited manual dexterity, the test strips cannot be so small as to make the strip difficult for the user to handle. The display image must be large enough to present the glucose measurement in an easily legible format, clearly viewable under a variety of lighting conditions (ECRI, 1997).

Quality of Construction

A relatively new type of electrosurgical return electrode has become available. It uses capacitive coupling to return electrosurgical energy used for cutting and coagulating of tissue to an electrosurgical unit from the surgical site on a patient. The return electrode is designed to disperse the electrosurgical current over its large surface area and to eliminate high-current densities in the electrosurgical current return path, which can cause a patient burn. This electrode is unique because of its large size (almost 2 feet by 3 feet) and is designed to be reused many times. The electrode consists of a large sheet of conductive fabric that is covered by a urethane insulating material. Because this device is reusable, it

likely will be exposed many times to sharp objects and other abuse in the operating room over its expected useful life. If penetrated by sharp objects or otherwise damaged, the conductive fabric could be directly exposed to the patient's skin, at which point electrosurgical current could concentrate and cause serious burns. This product, therefore must be resistant to tearing and other damage that might occur during normal use in the operating room (ECRI, 2000a).

Service and Support

PACS are complex, software-intensive systems that interface with many devices and systems throughout the hospital (see Chapter 102). These systems have many users, also throughout the hospital and sometimes from remote locations. They cannot be installed, operated, or maintained without significant support from the manufacturer. Many extensive software upgrades to these systems are expected throughout their useful lives. One critical criterion for an evaluation of these systems is for the manufacturer to have the ability to provide comprehensive, responsive, and reliable support from installation, day-to-day operations, routine maintenance and repairs, system upgrades, and user training (ECRI, 2000b).

Cost

Rarely is the cost of a medical device limited to the purchase price of the device itself. The additional costs could include accessories, service and support, installation fees, additional staff needed to run the equipment, reagents, annual software license fees, and financing fees. In order to do a true comparative analysis of the costs for several choices of medical devices or systems, all of the applicable costs must be considered over the expected life of the equipment, typically for at least five or seven years. When reagents or accessories are involved, evaluators must estimate the annual use of these elements in the equation and must come up with a projected annual cost for their use. The general cost criterion for any device evaluation is that a device should have a favorable life cycle cost as compared to other evaluated devices. The life cycle cost analysis must include all expected costs for the equipment, taking into consideration expected annual inflation rates and a discount factor to account for the changing value of money over the time of the analysis.

Testing for Compliance with Evaluation Criteria

Verifying compliance with essential criteria is relatively easy. Evaluators simply need to check with manufacturer specifications and to determine whether the devices being considered are specified to meet the essential criteria. If they do not, they can be immediately ruled out of the evaluation process. However, verifying the more specific performance and safety, ease of use, or other criteria is not that easy. In order to get it right and to avoid inappropriate or more seriously ineffective, overly expensive, or unsafe choices, a comprehensive effort is required. In some cases, physical testing is required. In other cases, qualitative assessments and comparative analyses must be used. With life cycle analysis, all costs must be identified, and projected volumes must be carefully estimated. The data then must be entered into analytical tools such as life cycle cost calculators to obtain results for comparison.

The person who does all of the research, testing, and analysis depends on the technology being evaluated and the hospital's previous history with the technology being considered. Older, more established, or simple technology might not require substantial hands-on analysis by the hospital. Consultation with an outside organization like ECRI for its experience with, and purchase advice for, the technology might be sufficient. Newer or more sophisticated (especially highly customized) technology like PACS or hospital information systems likely will need a dedicated team, including outside experts and nonbiased analyses, to determine how effectively the systems comply with the criteria, especially those that address the evaluating hospital's unique circumstances or customization needs.

It is important to include potential users on any assessment that occurs at the hospital. Users can provide valuable insights on any assessment of performance, device usability, or other characteristics and will be much more willing to embrace new technology that is eventually acquired if they believe that their opinion was sought and headed in the selection process. On many occasions, ECRI has observed technology being thrust upon clinical staff without its input. These situations create ill will between equipment selectors and users and often result in poor utilization of the new technology.

When ECRI conducts a comparative evaluation of a medical device, it uses detailed test methods and presents these and its findings in its monthly publication, *Health Devices*. Hospital equipment evaluators should look to this publication for guidance on ways to perform their analyses. In many cases, ECRI will have tested and presented results on the specific products being considered by the hospital. In this case, all that the hospital must do is to verify that ECRI's findings apply to the hospitals' unique circumstances. ECRI technical staff also can be used by the hospital evaluators for advice on ways to perform analysis and testing, which testing is most important to consider, and whether testing by an independent body is warranted for a particular device evaluation.

Dealing with the Findings

No technology is perfect. Some devices or systems might work well but are somewhat difficult to use. Another might work well yet might have a safety problem that is correctable with routine user intervention. Another might be the best performer, might be the easiest to use, and might possess the most desirable feature, yet it might be significantly more costly than the alternatives. These are the types of findings that equipment evaluators are likely to be confronted with at the end of the evaluation process. The evaluator's role is to assess the importance of each finding, then apply a weight or some other type of judgment scale to the finding, and tally the results to come to a final conclusion. The challenge for the evaluators is to determine the appropriate weight for each finding. And, unfortunately, one weighting system cannot be used for every class of device. For example, image quality is a critical factor when assessing digital radiography system. However, it is important, but not critical when assessing a physiologic monitoring system.

Equipment evaluators must look at the individual features of each evaluated technology and determine the features that are most important. Findings relating to the more important features can be assigned greater weight in the analysis. Evaluators then need to look at individual results in every category to determine whether any finding could affect the safety or overall effectiveness of the equipment significantly. Depending on the nature of the problem, a finding relating to an infrequently used feature could end up receiving a high weight in the device's final analysis. As an example, consider an infusion device evaluation where the device was found to work well, except for over a range of infrequently used flow settings. The accuracy at those flow settings was such that patients could receive a dangerous overdose of medication. Despite doing well on all of the frequently used and important settings, the system should be given an overall low rating for the evaluation. How low the rating is set would depend on how likely the infrequently used flow settings actually would be used at the hospital. This also could depend on the type of instructions that would have to be provided to the clinical staff on the problem, how likely the staff would follow the instruction over time, and whether there are other acceptable alternatives to the device with the accuracy problem.

Once the analysis is complete, evaluators should review their findings and conclusions carefully. The review should conclude that the hospital would end up acquiring a safe, effective, easy-to-use, clinically needed, and cost-effective device or system. If not, the appropriateness of the acquisition decision should be seriously considered.

Summary

Evaluating medical technology is a complex process. Many factors make the process so complex, ranging from the wide variety of devices purchased and used in hospitals, to the various settings and applications where devices are used, to the many different types of users of the equipment. Many hospitals do not have good processes in place to effectively evaluate their choices for medical technology, and subsequently they make inappropriate, and sometimes unsafe, equipment procurement choices.

In order to have an effective evaluation program, a process must be put in place to identify the true need for medical equipment. Once a true need for equipment has been identified, the features required by the hospital for the equipment must be identified. Only equipment with the required features should be considered for further evaluation. Detailed criteria then must be established for the remaining equipment under consideration. Resources like ECRI's Health Devices evaluations are valuable tools to use in establishing the evaluation criteria. ECRI's evaluation criteria often can be wholly incorporated into the hospital's evaluation process.

Once the evaluation criteria have been established, a careful process of assessing the equipment for compliance with the criteria can begin. ECRI and other outside resources can be utilized for this type of information. Hospitals likely will need to do some analysis on their own or with the assistance of outside experts, especially for highly customized equipment, such as clinical information systems. Once results have been obtained, a weighting system must be established to help the evaluating committee come to a final conclusion. Factors such as safety, overall performance, ease of use, likelihood of the equipment being used, clinical utility of the equipment, and cost should be important considerations in establishing the weighting system.

Evaluating Investigational Devices for Institutional Review Boards

Salil D. Balar

Beaumont Services Company, LLC
Clinical Engineering and Technology Management
Department
Royal Oak, MI

Most U.S. hospitals have Institutional Review Boards (IRBs). The United States Food and Drug Administration (FDA) defines an IRB as “an appropriately constituted group that has been formally designated to review and monitor biomedical research involving human subjects.” The FDA grants IRBs the authority to approve, require modifications in, and disapprove all research activities covered by FDA regulations. The department of Clinical Engineering and Technology Management (CE & TM) at William Beaumont Hospital (WBH) evaluates the safety and efficacy of investigational devices used in research studies before the devices enter into the stream of commerce. The role of the CE department in evaluating these devices varies from hospital to hospital. Too often, the IRB does not take advantage of the CE department’s expertise, thus posing a safety risk to the patients and medical device users involved in the studies. This chapter describes how CE & TM initiated, developed, and sustains a productive relationship with the Beaumont Hospital’s IRB, known at the hospital as the Human Investigation Committee (HIC). The CE & TM outlines the scope of the clinical engineer’s responsibilities, and describes a uniform procedure for evaluating and approving investigational medical devices used in IRB applications. It also suggests ways in which clinical engineers can adapt these concepts to their own situations.

A Cross-Functional Team

William Beaumont Hospital has been in compliance with IRB guidelines since the FDA began publishing them in 1981. However, it was not until 1988 that CE & TM began working with the hospital’s IRB. The CE & TM began service to a single research department regulated by the IRB and copied the IRB chairperson on reports to that department. At every opportunity, the CE & TM communicated the results of its evaluations for both patient and medical device user safety.

Gradually, the IRB began to recognize the value of the CE & TM to researchers, based on the following attributes:

- Extensive knowledge of the medical device industry’s problems and trends
- The ability to obtain objective information from the FDA and other regulatory resources
- High engineering skills and standards in device examinations and data analysis
- Expertise in envisioning the clinical use of medical devices in the context of clinical protocols

Over time, the IRB suggested that all researchers consult with it about the safety and efficacy of devices used in their studies. Recently, the William Beaumont Hospital IRB made the decision to require CE & TM approval of investigational devices before a trial begins, and it enforces compliance to CE & TM recommendations throughout the trial.

The CE & TM works with many of the hospital’s research departments, including cardiology, radiation oncology, radiology, vascular surgery, orthopedics, pediatrics, urology, and the eye institute. During the course of an evaluation, the CE & TM interacts with the hospital’s IRB chairperson and staff members. Information is exchanged with principal investigators and co-investigators, physicians, physicists, clinical research coordinators, and administrative managers in various research departments. CE & TM also communicates with manufacturers’ representatives, including their regulatory affairs experts and product-development engineers. Periodically, the director of CE & TM has an in-depth meeting with the IRB chair and vice-chair. At these conferences, the director requests feedback on the services provided and suggests new ways to expand the working relationship for mutual benefit.

The Scope of Evaluation Activities

It is within the scope of CE & TM responsibilities to evaluate investigational medical devices used in IRB projects. However, CE & TM does not assist the IRB with drug-

related studies. The following is a summary of the five most common circumstances under which CE & TM evaluates medical devices:

1. The IRB requests evaluation of a device for the first time.

CE & TM typically prepares a full evaluation report, described below,

- If the device needing evaluation is investigational (subject to IDE)
- If the device is being used for the first time at WBH in an investigational study for an IRB project

2. The IRB requests an evaluation update when there is a minor modification or upgrade to a previously evaluated device.

CE & TM evaluates the device and completes a short update report:

- If the device is investigational
- If the device has already been evaluated once
- If the device has a minor modification or upgrade

3. The IRB requests an evaluation of either an FDA 510(k) cleared device or a humanitarian use device (HUD), a device allowed by the FDA to be used under the Humanitarian Device Exemption (HDE).

CE & TM provides a memo in a format similar to an update report:

- If the device has 510(k) clearance
- If the device is being used in an investigational study for the first time at WBH
- If the chairperson of the IRB needs a memo addressing the risk of using the device

4. The IRB requests an evaluation of an FDA-approved device to be used for a different clinical application.

CE & TM provides a memo in a format similar to an update report:

- If a device is FDA-approved
- If a device has been used for one kind of clinical application in an investigational study at WBH, but will now be used for an entirely different clinical application
- If the chairperson of the IRB needs a memo addressing the risk of using the device.

5. The IRB requests investigation of an adverse event involving a device used during an investigation study.

CE & TM provides an adverse-event investigation report summarizing its findings and follow-up recommendations regarding the device.

The Evaluation Process

CE & TM’s evaluations focus on the safety and efficacy of the devices. It has found that the evaluation process can be divided into four steps: Initiation, information gathering, risk analysis, and preparation of a written report.

Initiation

When a research department needs a device evaluation, it provides CE & TM with the following items:

- A copy of the research protocol and a copy of the researcher’s application to the IRB
- A sample of the device

- The trial's anticipated start-up date
- Device packaging inserts
- Device specifications with operator and service manuals, if available
- Literature references
- A project number (to account for our time)

Research

The CE & TM gathers additional information from interviews, written records, and hands-on examination of the device. After reviewing the initial materials provided by the research department, CE & TM generates a list of questions for the investigator and manufacturer. For example:

- What testing is performed on the product?
- What material comes in direct contact with blood and what biocompatibility standards are followed for compliance?
- Have researchers experienced problems with the device to be used in the trial, or with similar products?

Next, CE & TM conducts its own information search. First, it reviews the Food and Drug Administration's Manufacturer and User Device Experience (MAUDE) database. The database contains reports of adverse events involving medical devices. The data consist of all voluntary reports since June 1993, user facility reports since 1991, distributor reports since 1993, and manufacturer reports since August 1996. The ECRI Health Devices database is searched next. ECRI provides information about product evaluations, alerts about technology-related hazards, and advice about technology acquisitions, staffing, and management (see Chapter 86). CE & TM then searches all other sources for any published product evaluations and adverse-event-investigation reports.

CE & TM clinical engineers closely examine the medical device under investigation. Step-by-step, they attempt to anticipate the modes of failure for each feature, using such techniques as Failure Mode and Effect Analysis (FMEA) (Stalhandske et al., 2003). Observations are compared to those described in published product evaluations and adverse-event-investigation reports.

Risk Analysis

Evaluating the product against established quality criteria and gathering relevant information is essential for an insightful analysis and a correct approval decision. In CE & TM's analysis, the quality of the manufacturer's instructions is assessed. Information about previous generations of the device is compared with what is claimed or known about the new version of the product. The manufacturer's compliance with common standards, such as those for sterilization and biocompatibility, are determined. Assessment also includes the risk associated with the circumstances or the conditions in which the device is made. The regulatory status of the device is confirmed. The suitability of the device for the particular proposed clinical application is verified. Only after the above tasks are completed does CE & TM formulate conclusions about the product's safety.

Report

In a written report, CE & TM does the following:

- Summarizes the facts gathered from interviews with researchers and manufacturers and from reviews of published information
- Describes the examination of the product
- Describes the other factors considered to reach conclusions
- Indicates approval or disapproval, and whether the approval is "full" or "conditional"
- Concludes with recommendations and/or stipulations

Recommendations for approved devices usually focus on user cautions. For example, it might be explained that the user should monitor temperature and pressure, check the device for damage and integrity of sterilization before use, or be aware of electrical, chemical, and fire hazards.

Recommendations for disapproved devices usually focus on a contingency plan. For example, the principal investigator might be requested to write a "failsafe" mode, to write patient instructions if the device fails during use, or to obtain more information from the manufacturer. If CE & TM cannot approve a device, the department works with the investigator and manufacturer to have the device or protocol modified as needed, so it can change the disapproval to an approval if possible.

The report is addressed to the IRB chairperson, and copies are made for the principal investigator, the director of the department that is responsible for the project, and other key personnel.

Challenges

The clinical engineer might encounter obstacles while developing a relationship with the hospital's IRB and an evaluation process that works for all involved. The following suggestions may mitigate these obstacles.

- Anticipate that the hospital's IRB may be uninformed or misinformed about the clinical engineering profession.
- Take the initiative to meet IRB members and researchers.
- Explain the benefits that clinical engineering would provide to the IRB and to research departments.
- Be prepared to suggest a procedure for working together but be flexible enough to incorporate the IRB's input.
- Expect the number of requests for your involvement to be limited at first.
- Anticipate that the investigators will sometimes have unrealistic expectations of the speed with which the evaluation and approval process can be performed.
- Encourage investigators to send all relevant information early to facilitate a timely completion of the evaluation. Anticipate that some manufacturers will be reluctant to provide a sample device. Explaining the need for the device and the method of evaluation usually will be sufficient to overcome the resistance.

Occasionally, a manufacturer insists on signing a confidentiality agreement before CE & TM can see a new device. Obtain the advice of your hospital's legal department in responding to such requests.

Summary

Clinical engineers are particularly suited for working with a hospital's IRB. Suggestions incorporated in this chapter provide ideas for initiating, developing, and sustaining a productive relationship with the IRB. Guidelines are presented to assist clinical engineering departments in determining the scope of their involvement and developing an evaluation procedure that will work for their particular hospitals. The clinical engineer who follows the recommendations described in this chapter will contribute to minimizing risks to patients and medical device users involved in research.

Defining Terms

Humanitarian Use Device (HUD): A device that is intended to benefit patients by treating or diagnosing a disease or condition that affects fewer than 4,000 individuals in the United States per year.

Humanitarian Device Exemption (HDE): An application similar in both form and content to a Premarket Approval (PMA) application, but is exempt from the effectiveness requirements of a PMA.

Investigational Device Exemption (IDE): An exception from the 510(k) clearance process under special conditions, such as when the device has a well-defined protocol or consent form, or can only be used for research purposes.

Premarket Submissions: For a medical device to be marketed in the United States, it must have clearance from the FDA. There are two types of FDA premarket submissions: A premarket notification 510(k) and a premarket approval application (PMA). Unless the FDA classification regulation specifically exempts a device, a premarket notification 510(k) submission is required for Class I and Class II devices. Depending on its type, a Class III device may require either a premarket notification 510(k) submission or a premarket approval (PMA) application.

Acknowledgements

The author thanks Paula Stachnik, medical writer, for her editorial support. He also thanks Michael Tanner, director of clinical engineering and technology management, for his insightful direction and guidance regarding regulatory-affairs compliance issues.

Section VIII

Medical Devices: Utilization and Service

Joseph F. Dyro

President, Biomedical Resource Group
Setauket, NY

Technology management entails medical device assessment, evaluation, selection, acquisition, inspection, service, education and replacement. The scope of medical device technology is broad, encompassing devices ranging from relatively simple, low-cost, disposable ECG electrodes to highly complex and costly picture archiving and communications systems.

To effectively manage this wide array of health care technology, clinical engineers must understand the rationale for medical device utilization, the constraints placed upon the technology by the facility, the patient, the operator and the environment, and the effect that those constraints have on device performance and safety. They must know what, why, how, where, and when devices are used in order to manage effectively. What was only a short time ago a biomedical engineering specialty concerned only with electronic monitors and defibrillators has returned to the original concept espoused by those early pioneers who saw clinical engineering as a profession that applied engineering skills to analyze and solve problems in the clinical environment, whether that entails purchasing the most cost-effective examination gloves or designing a new ambulatory care pavilion. Whether complex or simple, all medical devices fall within the purview of the clinical engineer, and they must be managed to ensure that the technology is performing satisfactorily at all times and without compromising patient or personnel safety.

This section places emphasis on medical devices that are used throughout various departments of primary- to tertiary-care hospitals, and some mention is made of technologies that might find use in the ambulatory, long-term-care, and home setting. While all medical specialties could not be covered with the limits of this handbook, this section contains a representative sampling of typical medical and surgical services. Rather than address in detail the design, theory of operation, specifications, and performance of a specific medical device, the authors give an overview of the types of devices that are commonly encountered in their clinical engineering practice in all areas of the hospital. Throughout this section, the reader's attention is directed to those particular aspects of a device's performance and safety that the author deems most significant in daily practice.

Miodownik (Intensive Care) describes the historical development of the intensive care unit (ICU) from facilities that treated casualties of war to those today that treat all life-threatening illnesses and injuries. Described as the CE's most challenging environment, the ICU accommodates patients often on the brink of survival intimately linked to a concentration of complex, expensive diagnostic and therapeutic devices utilized by dedicated, hard-working and occasionally overworked, overstressed, and inadequately trained personnel. Financial pressures and proliferation of medical technologies militate against utilizing the available technology in a thoughtful, deliberate, unhurried manner. Misuse, misapplication, and abuse are sometimes the consequences of overworked, overstressed personnel. Miodownik describes the significance of those devices that are typically encountered in the ICU, including monitors of physiological parameters such as temperature, blood pressure, heart rate, respiration, end-tidal carbon dioxide, arterial blood oxygen saturation; intraaortic balloon pumps; left ventricular assist devices; infusion devices; ventilators, and dialysis units. Clinical engineers are looked to as repositories of technical knowledge that is beyond that of the user nurse and physician. They must maintain a substantial level of expertise in the physics and physiology of measurements and therapies, knowledge of computer operating systems, networks and communications protocols, and the peculiarities of many different instruments, as well as an appreciation of way to keep all of these systems in operation.

Smith, Rane, and Melendez (Operating Room) describe the medical technology, surgical specialties, personnel, and the physical setting of a conventional operating room. The complex and dynamic interaction of these facets of the operating room is thoroughly illustrated, thus enabling the clinical engineer support this environment to more effectively. They begin with by describing the role of the operating room, typical operating room floor plan, surgical suite layout, and operating room infrastructure. They then list common and specialized device technologies such as electrosurgical units, anesthesia machines, surgical instruments, defibrillators, monitors, thermal support devices (hyperthermia machines), headlamps, tourniquets, lasers, imaging technologies, minimally invasive technologies (e.g., endoscopes and endoscopic instruments), and heart-lung machines. Lastly, they describe the CE's role in ensuring safety in the OR.

Melendez and Rane (Anesthesiology) expand upon the role of anesthesia in the OR as they give a thorough accounting of the role of the clinical engineer in supporting the delivery of that service by ensuring safe and efficacious medical devices. Starting with an overview of anesthesia, amnesia, and pain control, they move to a detailed description of typical technologies, such as the anesthesia machine and ventilators with associated humid-

ifiers, vaporizers, patient breathing circuits (carbon dioxide absorbers, scavengers, gas supplies, airway pressure, temperature and oxygen-monitoring systems). Airway-management tools, capnography, agent analysis, and principles of assisted ventilation are discussed.

The discussion of imaging technologies in the OR (Smith, Rane, and Melendez) is enlarged by Harrington (Imaging Devices), who describes the basics of radiation physics and the theory of operation of the X-ray machine (tube and housing, collimators, filters, and grids, film and film cassettes, and power supply). An overview of fluoroscopy and the video chain is given. Harrington then describes a typical table, overhead tube, control console, processors, multiloaders, and dry imaging. The film processor is explained, as are dark room films and daylight films. Specialty units are described, including mammography, tomography, bone-density analyzers, interventional radiology (special procedure rooms), and the cytoscopy room. He concludes with the portable C-arm and a general discussion of the techniques for effective management of imaging devices.

Machine vision can be defined as the "acquisition and processing of images to identify or measure the characteristics of objects." Rosow and Burns (Machine Vision) provide useful information on the three steps required for successful machine-vision applications: Conditioning, acquisition, and analysis. They illustrate this with two case studies: (1) the EndoTester—a virtual instrument-based quality control and technology assessment system for surgical video systems, and (2) a VabVIEW-based wound measurement system. This chapter underscores the application of clinical engineering in the research and design of diagnostic technologies.

The specialties of perinatology (DeFrancesco) (i.e., the care of the newborn before, during, and after birth), has made tremendous strides over the last few decades, owing largely to the rapid and simultaneous and synergistic advances in medical devices, pharmaceuticals, and clinical procedures. The flow of patients through a typical facility is described from prelabor, labor and delivery, and postpartum support areas. A typical floor plan for a labor and delivery area and individual room layouts are described. Changes in the patient environment (i.e., the building infrastructure) that have resulted in a safer and more efficient environment are noted. The tertiary-care facility often incorporates neonatal intensive care units and pediatric intensive care units to provide support for premature infants and critically ill infants in outlying hospitals without adequate support facilities. The special needs of security, data communications, climate control, medical gases, and vacuum-power distribution to support perinatal care is described. Explanations are given of most of the typical technologies such as maternal/fetal monitors, neonatal monitors, incubators, radiant warmers, apnea monitors, phototherapy units, ventilators, ultrasonic scanners, and the electronic medical record. The new therapeutic system of Inhaled Nitric Oxide (INOvent) delivery and monitoring is described.

Goodman (Cardiovascular Techniques and Technology) begins with some anatomy and discussion of cardiovascular disease. He then explains diagnostic technologies for cardiovascular disease, including noninvasive static and stress tests in diagnostic offices (e.g., electrocardiograms, phonocardiograms, and Holter monitors) and invasive diagnostic tests in the cardiac catheterization laboratory (e.g., cardiac output monitors and cardiac catheters). Hospital-based surgical interventions for cardiovascular disease in the operating room and cardiac catheterization laboratory, such as angioplasty, are explained. Cardiovascular care medical devices, including intra-aortic balloon pumps, cell savers, pacemakers, and defibrillators, are addressed.

The next chapter, Beds, Wheelchairs, and Other General Hospital Devices, explains that all medical devices must perform satisfactorily and must not pose a threat to patient or operator safety. Clinical engineering departments have shied away from such low-tech medical devices as beds, wheelchairs, and stretchers, perhaps because these items are not sophisticated enough and because the skill level of the department's staff members exceeds that required to service these items. Case studies demonstrate that the failure or misuse of the simplest general hospital medical devices can cause, and has caused, death and serious injury. Dyro shows that by matching skills and tasks, a clinical engineering department can cost-effectively manage these oft-forgotten devices to the benefit and safety of the patient population.

In the last chapter, a methodology is presented for determining the cause of a medical device malfunction. The generalized and systematic techniques recommended are effective in troubleshooting all medical devices, whether large or small, costly or inexpensive, mechanical or electrical, complicated or simple. The methodology applies to all causes of apparent medical device failure, including random component failure, device-device interaction, human factors design errors, operator misuse, and abuse.

Intensive Care

Saul Miodownik

Director, Clinical Engineering,
Memorial Sloan-Kettering Cancer Center
New York, NY

There has always been the perception that those patients closer to nursing stations fare somewhat better than their counterparts who are further away. The concept of the “intensive care unit” evolved from a series of medical needs as varied as the treatment of large numbers of shock casualties during World War II, nursing shortages in the late 1940s, and the polio epidemics of 1947–1948. The care and monitoring of such patients was more efficient, and survival improved when patients were grouped in a single location. By 1958, approximately 25 percent of community hospitals with more than 300 beds reported having an intensive care unit (ICU). By the late 1960s, most United States hospitals had at least one ICU. In 2002, there were approximately 6000 intensive care units in the U.S., treating 55,000 patients daily, with an annual budget of approximately \$180 billion. Several types of intensive care units exist, including surgical ICU, medical ICU, neonatal ICU, pediatric ICU, and burn ICU. The training of the staff accommodates the specific needs of the each population and the specialized equipment used. Many of the techniques and interventions are common to all types of ICUs (Marino, 1991).

A patient’s illness or trauma can rapidly become a life-threatening situation that demands immediate and continuous attention. ICUs are repositories of technology and expertise where patients can receive the treatment required for survival. In this arena, clinical engineers (CEs) are presented with their most complex and challenging environment. It is useful to categorize these technologies and equipment in the manner shown in Figure 88-1.

All four elements are required, to manage effectively any patient’s care. However, a patient who has been admitted to an ICU presents with a set of abnormal physiological conditions of varying severity that can suddenly change and become life threatening. Consequently, physiological parameters such as blood pressure, heart rate, blood oxygen saturation, and respiration are continuously monitored; laboratory results (e.g., blood chemistry, gases) and other information are frequently, though intermittently, obtained, integrated, and interpreted; and a therapeutic intervention is put in place, adjusted, or removed. Although this “closed loop” process is by no means automatic or unique to the intensive care setting, it represents an algorithmic approach to patient management that requires tight control and rapid response to emergent conditions. Consequently, the technologies that are required to implement these functions are often specialized for the ICU setting.

Monitoring and Diagnostics

Physiological monitoring in the ICU setting closely follows the patient’s cardiac, hemodynamic, and respiratory statuses. While early physiological monitors could view one lead of the ECG and, perhaps, an invasive blood pressure, today’s systems integrate a vast array of parameters into a relatively small monitoring device. A typical, full-featured, physiological monitor might contain a set of built-in monitored parameters or might have the ability to add plug-in modules to configure the unit as the clinical situation demands. Monitors located at the bedside are typically connected to monitors at a central station where one may observe the physiological status of many patients at once (see Figure 88-2). ICU monitors commonly include the ability to display the waveforms, values, and trends for the following parameters:

- 12-lead electrocardiogram (ECG)
- Arrhythmia monitoring and interpretation
- ST segment analysis
- Impedance based respiration
- One to three invasive blood pressures
- Noninvasive blood pressure
- Pulse oximetry (SaO₂)
- Two temperatures
- Thermal dilution cardiac output

The following additional monitoring functions are also available as separate units or modules that can be relevant to the management of ICU patient:

- End tidal CO₂
- Continuous cardiac output (CCO)

- Impedance based cardiac output
- Metabolic monitoring
- Real-time blood gas monitoring
- Mass spectrometry

Although provided as part of the therapeutic aspect of the intensive care unit, the life-support ventilator provides a full range of pulmonary monitoring parameters as well.

The admission of a patient to an ICU is often (but not always) prompted by compromises or threats to cardiac and/or respiratory function. Insufficiencies in these areas must be addressed rapidly. The delivery of oxygenated blood to body tissues is therefore the first concern of the ICU staff. ECG, pulse oximetry, and noninvasive blood pressure (NIBP) are physiological measurements that can be obtained immediately and noninvasively upon connection of the patient to the monitoring equipment.

Monitoring and therapy at this point become progressively more invasive with the addition of vascular access to measure internal blood pressures on both the arterial and venous side of the circulatory system. Catheters can be inserted into the pulmonary artery to obtain thermodilution cardiac output information (Trautman, 1988) as well as measurement of patient fluid load. Vascular access also provides a convenient site for obtaining blood samples for a variety of laboratory tests. Although attempted for many years, a practical and economical indwelling blood gas analysis catheter remains to be developed.

Additional diagnostic tools are often available in the ICU as well. It is common to find ultrasonic scanning and imaging systems as part of the unit’s armamentarium. Although 12-lead ECG acquisition is often part of the bedside monitor, a separate ECG machine is also available. Depending on the ICU size and census, the ICU also can own items such as dedicated, portable X-ray machines and blood gas analyzers. Because of the volatility of the patient’s medical condition, and the need to respond quickly to sudden changes, point-of-care blood chemistry machines, which are small enough to be positioned at a patient’s bedside, have been developed.

Bedside physiological data is often routed to a central station for display, printing, and alarm monitoring. In recent years, the importance of the central station as a location to be carefully watched for adverse patient events has diminished. Staffing in the ICU environment usually involves a high nurse-to-patient ratio. Most alarm events are recognized at the bedside, with the central station serving more as workstation for archival retrieval of alarm history and analysis of trends. The availability of inexpensive computer hardware has made possible the implementation of full disclosure systems that permit the archiving of all waveforms for a period of up to several days for all of the beds in the ICU. These are often packaged as software within the central station monitor. A consequence of the capabilities has been a reduction in the need and use of strip-chart recorders at the bedside or central station. There is little need to sift through yards of paper strips to find the event of interest because the full disclosure or alarm history record can be printed at will. The laser printer has become the *de facto* hardcopy device of choice.

Information Collection and Clinical Information Systems

Most, if not all, health care facilities in the 21st century have installed an information systems (IS) infrastructure that permits the dissemination of all manner of information to the hospital staff (see Chapter 97). Computer workstations are inexpensive and widely available, and they tap into the institution’s high-speed networks. Thus, ICU staff accessibility of such data as patient medical records and test results is assured.

As the patient is admitted to the ICU, information from his medical history and ongoing monitoring are collected and correlated. In today’s modern facility, a vast array of information is available to assess the patient’s condition. To this end (in addition or as part of the bedside monitoring), high-speed data networks route a large volume of information to the bedside for analysis. Past ECGs are retrievable from archived records and can be compared with the latest 12-lead ECG available at the bedside. Blood chemistry values are obtained, and relevant radiological and ultrasound images are retrieved electronically by way of a picture archiving and communications system (PACS) that is available for viewing near the patient’s bedside (see Chapter 102).

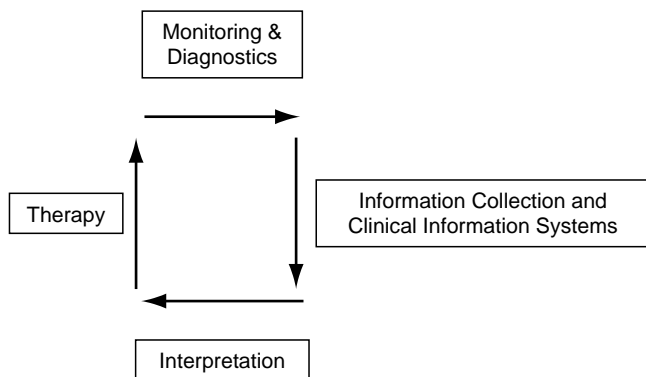

Figure 88-1 Four elements required for effective management of patient care.

The actual display devices for physiological monitoring and patient lab data are often identical. Increasingly, there has been a movement away from proprietary CRT monitors or thin screen displays in physiological monitoring. Many manufacturers have begun to use components and interfaces that are commonly and inexpensively available in the IS industry. Additionally, digital information is transacted using standard Ethernet protocols. This allows a certain degree of compatibility between physiologic monitoring systems and the patient's medical records. In many instances, parametric information from physiologic monitoring system passes to clinical information networks and workstations. To varying degrees, laboratory data are viewable on the physiologic monitors (see Chapter 98).

Interpretation

To address conditions that are life threatening and that require immediate intervention, several algorithms have been developed that, to a certain degree, address a given acute clinical situation. These algorithms can be taught to newer ICU staff and compensate to some extent for the experience that otherwise would be required. This distills the array of information into a simplified set of required parameters to treat a specific situation. A decision tree is followed with feed back information that is derived from the monitoring and diagnostic equipment.

Not all ICUs are managed the same way. There are two prevailing schools of thought regarding this issue. In some hospitals, when a patient is admitted to the ICU, most, if not all, of the patient's subsequent medical management is in the hands of a dedicated staff of intensive care specialists (IC specialists) whose responsibilities lie primarily in the ICU environment. This team of specialists includes physicians with specialties in such areas as pulmonary, cardio-vascular, infectious diseases, and internal medicine. Additional medical specialties are consulted as needed. Control of the patient's care is usually relinquished by the referring physician or surgeon. In other institutions, the referring physician might continue to monitor and adjust the therapy to the patient with the assistance of specialized nursing staff and technicians. The prevailing literature indicates that there may be benefits in terms of improved ICU survival rates, reduced length of stay, and a decrease in operating costs in an IC specialist-controlled ICU model.

The availability of this vast array of data and diagnostic tools does not necessarily translate into better outcomes for ICU patients. The complexity of a particular patient's

Figure 88-2 Physiological monitoring at the central station.

condition makes the interpretation of the data a less-than-automatic or intuitive process. Additionally, clinical studies that challenge certain prevailing ICU practices are constantly emerging in the literature. The relatively wide latitude of patient response to, and tolerance of, interventional procedures further clouds the issue. It cannot be stated with any clear degree of certainty that the introduction of advanced monitoring, therapies, and data management technology has resulted in a definitive decline in patient mortality. What advanced information technology has provided, however, is a streamlining of the information assembly process. This simplifies and, to some extent, reduces, the time required to assess and begin treating the patient.

Therapy

Patients who have been admitted to the ICU present with a host of problems that might or might not be life threatening. Severe dehydration, chest pain, and shortness of breath are common symptoms that dictate ICU entry. Upon admission, monitoring of basic vital signs is begun immediately and includes the measurement of electrocardiogram (ECG) (Plonsey, 1988), noninvasive blood pressure (NIBP) (King, 1988), and arterial blood-oxygen saturation (S_aO_2) (Welch, 1990). The resulting parametric information points to the first therapeutic interventions. Disturbances in the heart rhythm and rate are immediately visualized, blood pressure in the abnormal range identified, and low levels of S_aO_2 addressed. A peripheral intravenous (IV) line is started for the administration of medications, fluid support, and withdrawal of blood samples for diagnostic evaluation. Oxygen is applied by facemask to raise saturation levels. These are usual starting points, and many patients will require not much more therapy than this throughout their ICU stay. The patients are monitored, and the levels of therapeutic support are correspondingly adjusted, until the underlying disease process or condition is resolved. This type of patient represents a sizable percentage of the short-stay ICU population that is primarily being observed and requires minimal or moderate support during their stay. The more severely ill patients will undergo more radical and invasive therapies. Following are major categories of ICU therapeutic intervention.

Respiratory Care: Intubation, Mechanical Ventilation

Respiratory failure can be described as the inadequacy of the patient's intrinsic respiratory efforts to produce normal blood oxygenation and carbon dioxide clearance, as verified by arterial blood gas measurement. It can be caused by a host of factors, including infection, trauma, and paralysis. The primary consideration of mechanical ventilation has been to restore the patient's blood gas value to nominally normal levels. In spontaneous ventilation, the lungs inflate when negative pressure is created in the thoracic cavity by the downward displacement of the diaphragm. Until the mid 1950s, this was done with devices such as the iron lung, a container that surrounded the patient with his head protruding by way of an airtight collar (Mörch, 1985). This subjected the patient's body to a negative pressure, relative to the outside air, allowing the patient to inspire ambient air through his mouth as the iron lung cycled. This form of ventilation placed little stress on the patient's pulmonary system. He could eat, drink, and talk because his airways were otherwise unencumbered.

After the polio epidemics of the 1950s, positive-pressure mechanical ventilation became more widespread. In this mode, the lungs inflate when positive pressure is generated by the ventilator, forcing the lungs open and causing downward displacement of the diaphragm. Most often, this is done by delivering a volume of humidified, blended air and oxygen mixture by way of an endotracheal tube. Modern mechanical ventilators (see Figure 88-3) have a wide range of settings over a range of pressure limits such as O_2 percentage, tidal volumes respiratory rates, and positive-end expiratory pressure (PEEP) (Behbehani, 1995). This type of technology has been in place for more than 35 years, with various improvements in machine size, intelligence, display, modes of ventilation, interfacing, and data collection. However, there is a danger, long recognized, of ventilator-induced lung injury (VILI) or ventilator-associated pneumonia (VAP) with the indiscriminate use of positive-pressure mechanical ventilators. Overdistension of the alveoli, either by excessive pressures or volumes, can cause dangerous lung damage especially in the presence of high-oxygen concentration. This is often evidenced in the longer-term patient requiring higher levels of respiratory support. In addition, injury to the lung can produce a cytokine cascade effect that can cause damage to organs throughout the rest of the body. One approach to alleviate this problem is the use of permissive hypercapnia. Smaller tidal volumes are used to prevent lung distension and high airway pressure. This produces less CO_2 clearance, and the blood pH will be lower (more acidic), but this method can protect the lungs from permanent injury.

As an alternative, other ventilator technologies are available. High-frequency jet ventilation (HFJV), high-frequency positive-pressure ventilation (HFPPV), and high-frequency oscillation (HFO) all limit the volume and, hence, the pressure provided to the patient on each breath by operating at supranormal respiratory rates (Hamilton, 1988). HFJV and HFPPV operate in the realm of 100–200 breaths per minute, and HFO in the domain of 10–30 Hz. This is far in excess of the 10–30 breaths per minute encountered in spontaneous or mechanical ventilation. These high-frequency breaths produce lower peak airway pressures, possibly reducing lung injury.

Cardiac Care

Among some of the more frequently utilized devices in cardiac care are the defibrillator (see Figure 88-4), pacemaker, intra-aortic balloon pump (IABP) (Jaron and Moore, 1988), left ventricular assist device (LVAD) (Rosenberg, 1995), and extracorporeal membrane oxygenator (ECMO). For decades, life-threatening cardiac rhythm disturbances (e.g., ventricular fibrillation, ventricular tachycardia, and atrial fibrillation) have been successfully addressed utilizing defibrillators (Tacker, 1988). These devices have been standard in the ICU since their inception decades ago. Little has changed in their basic operation. They all deliver energy over a wide range of output energy and have had the ability to be synchronized (i.e., to perform ECG-synchronized cardioversion). Recently, however, the use of biphasic waveforms has been revisited. The assumption (not yet accepted in wide-ranging studies) is that more successful cardioversion can be achieved at lower energies, thus

Figure 88-3 Puritan-Bennett model 7200 ventilator.

avoiding potential damage to the myocardium. Additionally, the refinement of arrhythmia detection has allowed these devices to be automated, detecting dangerous cardiac events and firing the defibrillator without the need for operator intervention. Additionally, many of these units can be configured to perform transthoracic pacing.

Because of myocardial infarction, or for other reasons, patients sometimes develop temporary or permanent heart block, preventing the heart's conduction system from beating at an appropriately consistent rate. A pacemaker is typically utilized to correct this condition. Depending on the acuity of a patient's condition, the first-order intervention probably would entail the use of a transthoracic pacemaker. Pacing also can be done by inserting a pacing catheter in the right heart, which is then connected to a small, external pacemaker.

The aforementioned interventions effectively treat conduction or electrical defects that can arise spontaneously or in response to infection or myocardial infarction. The heart muscle is, for the most part, largely intact. When the heart muscle fails, additional measures must be taken, to sustain the patient's life. At the ICU bedside, this is accomplished by the use of an intra-aortic balloon pump (IABP) (Jaron and Moore, 1988). A special catheter is inserted into the aortic arch containing a balloon that can be rapidly inflated and deflated by a low-viscosity gas, usually helium. The timing of the balloon inflation is synchronized to either the patient's ECG or blood pressure waveform. Its primary purpose is to improve perfusion of the heart muscle by inflating the balloon as the aortic valve opens, providing additional backpressure to the carotid arteries and rapidly deflating it so that the rest of the body can be perfused. This procedure sustains the patient as the myocardium can recover sufficiently to pump on its own. In the event that a replacement heart is required, the procedure will extend a patient's life until a donor heart is available.

Alternatively, there are a number of LVADs that enhance the pumping action of the left ventricle until a donor organ is found (Rosenberg, 1995). They are surgically implanted in the patient's chest or abdomen and are managed by the ICU staff. Less widely used, though available also, is the extracorporeal membrane oxygenator (ECMO), or heart lung machine (Dorson and Loria, 1988). This device, used during coronary-artery bypass graft, can provide both respiratory and circulatory function, allowing the heart and lungs to be mechanically inactive for a time. Efforts such as this are extreme and require significant technical support during use.

Infusion Devices

Most ICU patients arrive with some form of vascular access and usually receive additional IV lines during their stay. Much of the therapeutic intervention and monitoring occurs via vascular access. Fluid management and drug delivery can be accomplished using gravity as the source of positive pressure to push liquids into the patient. Infusion rates are mon-

Figure 88-4 Defibrillator.

itored visually, and adjustments can be made to achieve the required goals. This approach is not viable when six to eight infusions are running simultaneously, with rates varying from 0.1 cc/hour, for certain pain medication, to hundreds of cc/hour, for rapid fluid replacement. This is handled now with a variety of programmable infusion pumps (Figure 88-5) and controllers (Voss and Butterfield, 1995).

Infusion pumps and controllers employ a variety of electromechanical mechanisms to regulate fluid flow to the patient. These include peristaltic or diaphragm pumps, syringe devices, and variable pinch clamp mechanisms that control gravity-driven flow. Usually, the tubing sets used by these devices are dedicated and not interchangeable. Infusion pumps with a wide range of rates (1–999 cc/hour) have been available for decades. Modern infusion devices have a wide range of programmable infusion rates and extensive alarm capabilities. Features include proper set placement detection, pressure limits, proximal and distal occlusion alarms, end of infusion alarm, and programmable keep-vein-open (KVO) rates. Additional safety features to prevent unrestricted free flow of IV fluid to the patient are incorporated as well. In order to avoid medication errors, systems that will associate pharmacy requisitions, the infusion device, and patient identification are being developed. Additional intelligence in such systems will identify patient sensitivities, incompatibilities between infused medications, and violation of nominal drug concentrations and infusion rates.

Dialysis: Kidney and Organ Support

The sickest ICU patient will begin to manifest failure in one or more organs. Acute renal failure (ARF) is not uncommon in the ICU setting. ARF occurs in approximately 5% of all hospitalized patients and, historically, has been associated with a high risk of mortality. Following the introduction of dialysis therapy more than 50 years ago, patient mortality dropped from 90% to 50%. However, mortality in the intervening years has not improved from the 50% level. In ICU patients presenting with other co-morbidities, the mortality rate

Figure 88-5 Abbot Plum XL infusion pump.

is between 50% and 80%. Although the etiology of ARF varies, it is often associated with a reduction in urine output and a drop in systemic blood pressure. Waste products accumulate in the blood, electrolyte levels become abnormal, pH usually drops, and edema sets in.

Initially, ARF was treated in the same manner as chronic renal failure, with intermittent hemodialysis. This approach quickly removes the metabolite, electrolyte, and fluid imbalance. However, these levels vary widely because the body continuously generates their production between dialysis sessions. Consequently, there has been a move toward continuous renal replacement therapy (CRRT) (Galletti et al., 1995). In this mode, renal function is supplied continuously while the patient recovers. There are several different CRRT modalities. Historically, arterial circulation was used to provide the force to move blood across a dialyzer cartridge. Because of the need for arterial access and inherent complications and the technical improvement in venovenous therapies, these methods have been largely abandoned. The venovenous modalities differ primarily in the methods of clearance. Slow continuous ultrafiltration (SCUF) is a method employed to remove volume by taking off fluid filtered by a dialysis membrane by convective force. Continuous venovenous hemodialysis (CVVHD) provides clearance using diffusive clearance by running dialysate across the membrane. Continuous venovenous hemofiltration (CVVHF) removes fluid by convection (as in SCUF) and then provides replacement fluid back to the patient. Finally, continuous venovenous hemodiafiltration combines the clearance properties of CVVHD and CVVHF. These approaches are provided by bedside machines incorporating the required pumps, control instrumentation, filters, and fluids.

Clinical Engineering and the ICU

Perhaps the most complex and technically challenging hospital environment is the ICU. Traditionally, CEs have been involved in medical device evaluation, inspection, maintenance, layout, design, and integration of the various instrumentation systems. As the devices' and systems' complexity has increased over the years, clinical engineers have been looked to as repositories of technical knowledge that is beyond that of the users (i.e., the nurses and physicians). This requires maintaining a substantial level of expertise in the physics and physiology of measurements and therapies; knowledge of computer operating systems; networks and communications protocols; and the peculiarities of many different instruments as well as an appreciation of ways to keep all of these systems in operation. The many interactions and safety issues of the various monitoring and therapeutic instruments must be understood and translated so that the CE can provide answers to questions posed by the clinical staff, whose responsibility is the care of the patient, not the technology.

89

The operating room is an exciting location in which to apply the principles of engineering. The surgical environment encompasses an extensive arrangement of medical technologies and processes. The clinical engineer must apply the principles of several engineering disciplines to support an efficient, productive, and safe operating room.

This chapter describes the medical technology, surgical specialties, personnel, and physical setting of a conventional operating room. The complex and dynamic interaction of these facets of the operating room is thoroughly illustrated, thus enabling the clinical engineer to support this environment more effectively.

The Role of the Operating Room

Surgery is the diagnosis and treatment of medical injuries, diseases, and deformities by manual or operative means. It is a fundamental service that the health care facility pro-

vides to a community. A vast assortment of surgical procedures is performed to treat the medical conditions within the scope of health care.

A surgical procedure is a delicate and complicated undertaking. It must be performed in a controlled environment with numerous technical resources and a staff of medical professionals and support personnel. Depending on the patient and the nature of the surgical procedure, surgical cases are characterized in one of three ways: Inpatient, outpatient, and same-day. Inpatient procedures are performed for patients who have been admitted to the hospital. Outpatient procedures are generally for those undergoing minor surgical procedures. In those cases, the patient typically will undergo a local anesthetic and will be admitted and released in the same day. Same-day surgery consists of more extensive cases than outpatient procedures and might include general anesthesia. However, the patient is also discharged in the same day. The operating room is the location in a health care facility that is equipped for the performance of surgery. Patients who require invasive treatment are transported to this department to undergo induction of anesthesia, the surgical procedure, and resuscitation. It is a technologically advanced area filled with complex

equipment, highly trained professionals, and stringent environmental controls. For the scope of this chapter, the term “surgical suite” will be used to refer to the individual room where a surgical procedure is performed. The “operating room” will signify the entire department, within the health care facility, in which the operating suites and supporting areas are located.

A typical hospital comprise numerous departments that provide a wide range of services. The operating room (OR) plays an important role in a hospital and in the overall process of providing patient care. The following lists outline the typical steps for a patient who is undergoing a scheduled surgical procedure, as well as an unscheduled procedure. It is meant to demonstrate methods in which a surgical procedure is arranged, and the relationships among hospital departments.

Scheduled Surgery

- The patient consulted a primary care physician.
- The primary care physician made a diagnosis and directed the patient to consult a surgical specialist.
- A surgical specialist diagnosed the condition and confirmed the need for surgical treatment. Images from the radiology department and test results from the medical lab aided in the diagnosis.
- The surgery date was scheduled, and OR time was booked.
- The patient was admitted to a pre-admitting test center to review the medical history and to undergo various tests.
- An anesthesiologist studied the patient’s medical history and planned the method of anesthesia.
- The patient was sent to the pre-operating area (induction room), where she was prepared for surgery, and anesthesia was initiated.
- Surgery was performed in a surgical suite.
- Following surgery, the patient was delivered to the post-anesthesia care unit (PACU) to recover from the effects of anesthesia.
- The patient was delivered to a care unit for complete recovery.
- The patient was discharged from the hospital.
- The patient made periodic visits to the hospital for physical rehabilitation.

Unscheduled (Emergency) Surgery

- The patient placed an emergency call, and an ambulance was dispatched.
- The patient was delivered to the hospital’s emergency department.
- The ER physician ordered the patient be transported to the radiology department for imaging and sent samples to the medical lab for analysis.
- A surgical specialist was consulted to aid in the diagnosis.
- The patient was transported to the pre-operating area (induction room), where she was prepared for surgery, and anesthesia was initiated.
- Surgery was performed in a surgical suite reserved for emergency cases.
- Following surgery, the patient was delivered to the PACU to recover from the effects of anesthesia.
- The patient was delivered to the intensive care unit for complete recovery.
- The patient was discharged from the hospital.
- The patient made periodic visits to the hospital for physical rehabilitation.

A wide range of surgical procedures can be performed in an operating room. The surgical specialties of a particular hospital are based on the resources and medical scope of that health care facility. The following is a list of some surgical specialties that are commonly found in a hospital’s operating room. A brief description of each specialty is included.

General Surgery

This form of surgery includes a broad spectrum of surgical care that involves largely the surgical management of diseases of the bowel, gallbladder, stomach, and other digestive organs.

Thoracic and Cardiovascular Surgery

Thoracic and cardiovascular surgery concerns the diagnosis and treatment of disorders of the thorax. The thorax is the upper part of the trunk between the neck and the abdomen, containing the chief organs of the circulatory and respiratory systems, such as the lungs and heart. Two major types of thoracic surgery are classified as pulmonary (i.e., pertaining to the lungs) and cardiovascular. Cardiovascular surgery treats diseases and conditions of the heart and the blood vessels of the entire body. Common cardiovascular procedures include coronary bypass surgery, aortic or mitral valve replacement or repair, and aneurysm repair.

Neurosurgery

Neurosurgery is the specialty of surgery that addresses the diseases and disorders of the nervous system. Within the realm of neurosurgery are the brain, spinal cord, and associated vascular supply. Common procedures include cervical fusion. Disorders commonly treated by neurosurgeons include intracranial tumors, vascular malformations, carpal tunnel syndrome, spinal cord injury, and stroke.

Orthopedic Surgery

Orthopedic surgery treats and corrects deformities, diseases, and injuries to the skeletal system, its articulations, and associated structures. Some examples of orthopedic surgery include hip and knee replacement, cartilage repair, and fracture repair.

Plastic Surgery

Plastic surgery is concerned with the repair, restoration, or improvement of lost, injured, defective, or misshapen parts of the body, caused by congenital defects, developmental abnormalities, trauma, infection, tumors, or disease. It is generally performed to improve functions, but it also is done to approximate a normal appearance.

Gynecology

Gynecology involves the physiology and disorders primarily of the female genital tract, as well as female endocrinology and reproductive physiology.

Urology

Urology is the study, diagnosis, and treatment of diseases of the urinary tract in both sexes, and the genital tract in the male.

Burn Treatment

Burn treatment is surgery performed to treat and manage burn injuries by reconstructing damaged tissues and improving functionality of the damaged area. A burn team might include plastic and general surgeons.

Pediatric Surgery

Pediatric surgery is concerned with the health of infants, children, and adolescents.

For the purpose of this chapter, the setting for any of the following procedural areas can be characterized as a surgical suite. In many cases, the equipment and facility requirements that are present in these areas are similar to those found in a conventional operating room environment.

- Labor and delivery
- Endoscopy
- Ophthalmology and otolaryngology procedure rooms
- Dental surgery
- Radiology suites, including interventional radiology and radiation oncology
- Interventional electrophysiology
- Treatment rooms in which minor procedures are performed

Operating rooms, large and small, rely heavily on medical personnel and support staff to carry out a wide variety of tasks. The following is a list of some of the employees who might be found working in, or providing a service to, the operating room.

- Physicians and anesthesiologists
- Registered nurses, circulating nurses, scrub nurses, nursing assistants, and surgical technicians
- Clinical engineers, biomedical engineering technicians, and anesthesia technicians
- Schedulers, record keepers, patient transporters, turnover team, purchasers, and administrators

Operating Room Floor Plan

The floor plan of a well-organized and safe OR involves a great deal of research and planning. It is a complex environment with numerous design criteria. The layout of the facility directly affects user productivity and satisfaction. The OR must be arranged in a manner that is conducive to the flow of patients, staff, and equipment. It also must include space for functional support areas that are common to most ORs, such as instrument processing, technical support, and equipment storage areas. It is necessary for clinical engineers to have knowledge of the OR layout and design issues. Clinical engineers, as technical experts of medical technology and the environment in which it is used, also may serve as a valuable resource in the design of an OR.

The arrangement of surgical suites often reflects a hospital’s available space and surgical requirements. Several OR floor plans have been developed to utilize available space and maximize productivity most ideally. The L- or T-shaped single-corridor layout is common in smaller ORs. Larger facilities typically utilize the multiple-corridor layout, with the clustering of surgical suites by surgical specialty. (Bronzino, 1992). Grouping surgical specialties together aids in the efficiency of sharing common resources.

The location of functional support areas that serve the OR is another important consideration in a floor plan. The efficiency of these services is enhanced when the distances that must be traveled are minimized. The following is a list of some functional support areas that are commonly found in, or adjacent to, the OR.

Induction and Pre-Operative Holding Areas

Induction and pre-operative holding areas are utilized to prepare the patient for surgery, and the administration of anesthesia. These services are located either immediately adjacent to the operating room or within the department. The procedures and services performed in these areas will vary from hospital to hospital. The holding areas at some facilities are used simply to prepare the patient for delivery to the surgical suite, and other hospitals might utilize this area to fully anesthetize the patient.

Scrub Stations

Scrub stations used for hand washing contain sinks and cleaning supplies and are common to all ORs. Two scrub positions must be located adjacent to the entrance to each surgical suite.

Control Desk

The control desk is the communication center of the operating room. Arrangement of the case schedule is a primary function of the control desk. This is vital for the efficiency and productivity of the OR. Several things must be considered when planning the schedule. The scheduler must coordinate the urgency of surgical cases, surgical location, time considerations, patients, surgeons, anesthesiologists, support staff, equipment and supply availability, and post-anesthesia care. The control desk also might be involved in patient billing and recordkeeping.

Technical Support Services

Technical support services are vital to the productivity of the OR. Support for operating room technology must be immediately available to ensure the efficiency and safety of the surgical environment. Support groups serving the OR include anesthesia technical support and clinical engineering (see Figure 89-1). Anesthesia technical support is located within, or in the immediate vicinity of, the OR. The anesthesia workroom is primarily used for cleaning, testing, and storing anesthesia equipment. In larger facilities, clinical engineering support workrooms also might be situated within the OR. Later in this chapter, the responsibilities of the clinical engineering department will be discussed in detail.

Patient Support Service Areas

Patient support service areas include personnel, equipment, and supplies used to provide assistance to a variety of operating room functions. Space must be incorporated into the operating room floor plan to accommodate services such as equipment or patient transporters, orderlies, and nurse's aides.

Housekeeping Areas

Housekeeping areas are the workspaces for housekeeping and turnover team personnel, equipment, and supplies. Turnover team members are responsible for cleaning and setting-up surgical suites between cases.

Pharmacy

The pharmacy is included in the overall design of a health care facility to provide medications for patient care. Hospitals of considerable size can include a pharmacy within the operating room.

Instrument Processing

Instrument processing can be managed in a variety of ways, depending on the resources and preferences of a particular institution. Regardless of the sterilization method, a process must be present for delivering contaminated instruments to the processing area and redistributing the appropriate instruments to the surgical location. Sterilization methods can be divided into two categories: Centralized and decentralized.

A centralized processing department is designed to serve a large volume and can be located within the operating room. Smaller hospitals sometimes utilize a centralized processing department that serves the entire facility. Centralized instrument processing can employ an assortment of sterilization processes. The two most common methods include steam sterilization and ethylene oxide (EtO) sterilization. Autoclaves are devices that sterilize instruments using steam, with temperature, exposure time, and pressure as variables. Variables in EtO sterilization are EtO gas concentration, moisture, temperature, and time. Dry-heat sterilization and chemical sterilization are other methods of instrument processing that can be utilized in health care facilities.

Decentralized instrument processing is the practice of sterilizing instruments inside, or within the immediate proximity of, a surgical suite. Perhaps the most common method

involves the use of autoclave technology. An autoclave can be designated for each operating suite or shared among a cluster of suites. Table-top sterilizers are used for flash sterilization located in common areas in the operating room. They are autoclavable at around 270° F for 3 to 5 minutes

Materials Management

A hospital also must allocate space for the delivery, storage, and distribution of supplies to the operating room. The process of waste disposal also must be accommodated. Trash and biological waste must be properly stored, handled, and eliminated. In addition, the operating room must establish a manner for processing surgical drapes, scrubs, and other linens used in the surgical environment.

Equipment Storage Areas

A common dilemma is the lack of sufficient storage space. The operating room layout must include areas for the storage of medical devices. Large devices, such as stretchers, spare anesthesia machines, and X-ray equipment, must be stored in accessible locations where they will not clutter or obstruct hallways.

Other areas

Functional areas that also can be located in or near the operating room include dark rooms, conference areas, and locker rooms.

Operating Room Facility Infrastructure

The operating room is a complex environment that requires precise climate control and numerous utility services. The following is a list of utilities services that are present in an operating room. A description of each utility is included.

Climate Control

The purpose of a heating, ventilating, and air-conditioning (HVAC) system is to provide and maintain environmental conditions, including proper airflow, heating, and cooling within a certain area or the entire hospital (Hyndman, 2003). Types of HVAC systems include variable air volume, multizone systems, displacement ventilation, and water-loop heat pumps. An HVAC system mainly consists of an air/water supply system, filters, heating and cooling coils, compressors, fans, motors, exhaust and evacuation systems, air ducts, vents, and control mechanisms. It can provide heat and ventilation to the entire hospital with provisions for controls for individual zones (e.g., the OR), or each zone can have their own HVAC system and associated control. The control mechanism is an integral part of a highly efficient HVAC system. The controls monitor, display, and allow the user to regulate various parameters, including temperature, pressure, and humidity. Precise control over temperature and humidity is important in the operating room. For example, a clinician must be able to adjust the temperature of the operating suite for surgical specialties such as pediatrics and orthopedics, where higher room temperatures are desired in order to help maintain patient temperature. Some cases, such as burn treatments, require a higher humidity.

The OR requires specialized criteria for the ventilation system as well. The surgical area must be replenished with fresh air at regular time intervals time to maintain a safe and sterile environment. A minimum of three air changes per hour of outdoor air, and 15 total air changes per hour, is required (AIA, 1996). A positive pressure must exist between the operating room and adjacent areas, to prevent the inflow of contaminated air. The ventilation system also should be designed so that there is no recirculation of air from room to room.

Adequate filtering is another important criterion of the ventilation system. A hospital-grade high efficiency particulate air (HEPA) filter is installed at the location where the air is drawn in, to filter debris and to control airborne infection. Hospital-grade HEPA filtration is constructed with an air-intake grill to catch larger debris such as leaves, seeds, and insects. Next is a layer composed of fibers to remove smaller objects like dirt and dust. Finally, a corrugated fine-mesh removes particles such as pollen, dust, and viruses.

Electrical Power Distribution

The prevalence of electrical devices for the diagnosis and treatment of patients has made electrical power distribution one of the more important systems in modern medical facilities (see Chapter 109). The nature of the operating room environment demands a particularly elaborate set of requirements (NEC, 2003). Electrically powered devices surround the patient and perform a wide range of vital functions. Therefore, proper design and maintenance of the electrical power system are essential, to ensure the safety of both the patient and the clinician. As the need for a continuous power is essential throughout a hospital, electrical systems must comprise at least two sources of power. The typical primary power sources are public utility lines. To provide for the continuous supply of power to the critical areas of the hospital, an alternate, or emergency, source of power is necessary. In the event of an interruption, hospitals are required to have an in-house alternate source of power, such as a generator.

The operating room is densely populated with electrically powered devices. Individual surgical suites must be supplied with enough electrical wall outlets to accommodate the equipment, and these outlets must be in locations that are conveniently accessible to the clinician. Wall outlets in a health care facility deliver power to equipment using a three-wire configuration of hot, neutral, and ground wires. The ground wire protects patients and staff from electrical hazards by providing a low resistance pathway to channel fault or leakage currents away from an electrically powered device to ground. Some surgical techniques and instrumentation bypass the patient's body resistance, thus increasing the

Figure 89-1 Clinical engineering department engineers and technicians support the OR.

patient's susceptibility to electrical energy from external sources. Minimizing the electrical energy to which a susceptible patient is exposed is prudent. For additional information on electrical safety, see Ridgway (Chapter 65) and Baretich (Chapter 109).

Although most equipment is designed to operate on the same power requirements, the facility also must be prepared to accommodate devices that require varying power consumption. While most wall receptacles provide 115 volts, some electrical devices, such as lasers and X-ray equipment, require 230 volts to operate (see Chapter 91).

In the past, the use of combustible anesthetic gases (e.g., cyclopropane and ether) created a volatile environment that demanded additional safety measures. It was essential to reduce the likelihood of a static discharge (spark) that could lead to an explosion in the operating suite. Although the risk of explosion is not typically an issue today, it has played an important role in the design of electrical power systems in many existing operating rooms. For example, power outlets have typically been installed approximately four feet above floor level because volatile explosive agents tend to settle in the air. Special plugs, termed "explosion-proof," were also commonly installed on power cords that, when plugged in, created an airtight seal. Conductive flooring is also commonly found in operating rooms. This technology was installed to eliminate the electrical isolation of equipment and personnel in an operating suite. Electrical isolation between objects is conducive to the build-up and potential discharge of static electrical charge. Isolated ungrounded power systems, line isolation monitors (LIM), and ground-fault circuit interrupters (GFCI) are further examples of technologies employed in operating rooms to reduce the risk of explosion in the presence of combustible anesthetic agents. These technologies also serve to reduce the risk of explosion from electrical shocks resulting from stray (leakage) current.

An isolated ungrounded power system is an electrical power distribution system in which all of the current-carrying conductors are isolated from ground (and earth) by a high impedance (Feinberg, 1980). The most common and economical method of isolation is to use an isolating transformer. In a properly installed system, no hazardous current will flow from either conductor to ground, but the two conductors will function as though they were connected directly to a ground. This is especially useful in a "wet environment" such as the operating room, where liquid spills and standing water increase the risk of electrical hazards.

An LIM displays the degree of electrical isolation in an isolated ungrounded power system. It provides an early warning system of possible leakage or fault currents from either of the current-carrying conductors to ground. A GFCI also serves to protect patients and staff members. This technology monitors the ground fault current and interrupts the power to the electrical receptacle when the current exceeds a preset limit. Although LIM technology is more expensive, one advantage over the GFCI is that the LIM will alarm when a fault is detected, but will not interrupt electrical service.

Gas Pipelines

Pressurized gases must be distributed to locations throughout the health care facility (see Chapter 110). Medical gases such as oxygen, nitrous oxide, and medical air are particularly important for the administration of anesthesia in the operating room. Medical gases are stored either in metal cylinders or in the reservoirs of bulk gas storage and central supply systems. The central supply system is the source of medical gases that are distributed via the facility pipeline system. The number and location of wall outlets in the operating room varies, depending on facility design and surgical specialty. Figure 90-2 shows a wall outlet for nitrogen commonly used to power pneumatic tools such as saws and drills.

The method of storage for the central supply of oxygen depends on the demands of the facility. Smaller facilities tend to store oxygen in a series of cylinders connected by a manifold or high-pressure header system (Ehrenwerth and Eisenkraft, 1993). Larger facilities store their bulk oxygen in pressurized liquid form, which enables the hospital to store more oxygen in a smaller space. The central supply of medical air is most commonly generated by air compressors, stored in a reservoir, and delivered to the piping system. Other sources include pressurized cylinders or a proportioning system that mixes the appropriate amount of oxygen and nitrogen from central sources. The nitrous oxide supply systems include the cylinder manifold system or a bulk liquid storage system similar to the one used for oxygen system (Ehrenwerth and Eisenkraft, 1993). All central supply systems for medical gases must be designed with a separate reserve system. Details con-

cerning the use of medical gases in anesthesiology are discussed elsewhere in this handbook (see Chapter 90).

Nitrogen and carbon dioxide can be piped into the operating room, as well. Nitrogen, primarily used for gas-powered equipment, is stored as a series of pressurized tanks connected by a manifold. Carbon dioxide is also typically stored as a cylinder manifold system.

Vacuum

The central vacuum system is another essential utility that must be piped into the operating room. The system is vital to both surgery and anesthesia. It provides pressure for drainage, aspiration, suction during surgical procedures, and the scavenging of waste gases from the anesthesia machine breathing circuit. A health care facility must have two suction pumps, each individually capable of handling the overall demand.

Lighting

Lighting is an essential utility in a health care facility. The operating room requires special attention to lighting because of the small-scale delicate tasks that must be performed. Although, the choice of a surgical light is subjective, several characteristics must be addressed. The criteria include light intensity, light color, focusing capability and range, degree of shadow production, heat production and dissipation, choice of mounting, lamp head maneuverability, and ease of cleaning (Bronzino, 1992).

Communication

The speed and reliability of communication in the operating room is vitally important. Communication systems are becoming increasingly complex with the continual advances in networking and wireless technology. Fundamental modes of communication such as telephones, paging systems, and intercoms are common in operating rooms.

Advances in computer technology and network systems have had a profound effect on the communication systems within the operating room environment. E-mail, Internet access, online scheduling, and patient databases have vastly improved the quantity and quality of exchanged information. See the section on information, in this handbook.

Fire Protection

All health care facilities must be equipped with a fire protection system. The fundamental elements of such a system include smoke detectors, alarms, a sprinkler system, and automatically closing doors to contain the fire. The hospital staff must have an established evacuation plan for patients and staff. Several operating room fires occur each year. The combination of an oxygen-enriched atmosphere, fuel source (e.g., drapes, endotracheal tubes, and the patient) and ignition source (e.g., electro-surgical units and lasers) have produced catastrophic fires (de Richmond and Bruley, 1993; NFPA, 1994).

Surgical Suite Layout

A well-designed surgical suite provides ample space for staff and equipment. It encourages a smooth flow of people and materials within the room. While the layout of an individual surgical suite varies by surgical service, all suites share some characteristics, as described in below.

The size of the operating suite should reflect the space required by the patient, staff, and equipment to carry out the surgical procedure. The standard surgical suite is at least 400 square feet. Surgical suites that require specialized equipment or additional personnel can be significantly larger. It is important to provide space so that sensitive medical equipment is not positioned in high-traffic areas. The shape of an operating suite can take on a variety of forms, (e.g., square, rectangular, round, or oval), depending on design preferences and overall operating room layout.

The surgical table is typically oriented in the center of the room, with the surgeons positioned along the side of the patient. The scrub nurse is positioned in an area where both the instrument table and the surgeon's outstretched hand are within reach. The anesthesiologist and anesthesia equipment are generally located at the head end of the table. This allows the anesthesiologist to have access to the patient's airway. The anesthesia equipment also must be positioned near medical gas, vacuum, and power outlets that can be located on a wall or column. Other devices, such as defibrillators, electro-surgical units, video towers, and bypass machines, are located further outside the surgical field. Figure 89-3 shows a typical layout of an operating room.

The surgical suite also must provide accommodations for storage. Commonly, cabinets, shelving, and carts will line the walls of a surgical suite. In addition, surgical suites are usually equipped with communication equipment. Computer, intercom, and telephone access are standard in modern surgical suite layouts.

Common Operating Room Technologies

The following is a list of typical medical technologies commonly found in the OR. A brief description of each technology is included.

Furniture

Furniture is utilized extensively in the operating room and serves a wide range of functions. Patient beds are employed for transporting patients and as an adaptable platform for performing surgery. Transport beds, or stretchers, are designed with side rails and large casters to safely transport patients within the hospital (see Chapter 95).

Figure 89-2 OR wall outlet for nitrogen gas.

Figure 89-3 Typical OR layout showing OR table, overhead lights, anesthesia machine and monitors, medication and supplies cart, storage room, and wall outlets for gases.

Surgical beds are valuable tools for patient positioning during surgery. In order to accommodate various procedures, surgical beds are more substantial and complex than transport beds. Modern beds are equipped with mechanical, electronic, and hydraulic systems that allow clinicians to position a patient in numerous orientations, such as raising or lowering the height, tilting to the left or right, Trendelenburg (head down, legs up), and reverse-Trendelenburg. Surgical bed accessories include arm support boards, leg supports, foot extensions, restraints, and padding. They also can be outfitted with a wide variety of specialized surgical positioning devices, such as neurosurgical headrests, radiolucent tops, and the Andrews Frame used for spinal surgery.

Other standard items of furniture in the OR include instrument tables, intravenous (IV) poles, waste storage bins, stools, and chairs. Racks, carts, and shelving, used to store medical supplies, surgical supplies, and instruments, are also common in a surgical suite.

Surgical Drapes

Surgical drapes are used in the OR to protect the patient, clinicians, and equipment. Drapes can be made of cloth or paper, and reusable or disposable. Figure 89-4 shows a surgical procedure underway with the patient draped. Important characteristics include barrier protection effectiveness, resistance to ignition, and durability. Surgical drapes are employed to provide a physical barrier that protects the surgical field from contamination. An "ether screen" is the wall of drapes set up in order to provide a barrier between the anesthesia work area, at the head of the patient, and the surgical field. Drapes are also placed in the surgical field around the incision site to cover the patient and to collect fluids. They also can be used to wrap sterile surgical instruments and to cover equipment in the surgical suite.

Anesthesia Equipment

The delivery of anesthesia requires a gas delivery system, as well as continuous and detailed monitoring of patient physiology. The anesthesia machine is used to deliver a known mixture of gases to the patient. Three main sections of the anesthesia machine are the gas supply and delivery system, the vaporizer, and the patient breathing circuit (see Chapter 90; Calkins, 1988; Paulsen, 1995; Dorsch and Dorsch, 1984).

A variety of technologies are employed by the anesthesiologist to monitor the physiology of the anesthetized patient. Physiological monitoring equipment includes electrocardiograph monitors, pulse oximetry, invasive blood pressure monitors, noninvasive blood pressure monitors, temperature monitors, respiratory gas monitors, and electroencephalo-

Figure 89-4 The surgical team at work on a draped patient.

graph monitors (see Chapter 98). Other devices utilized by the anesthesiology department include infusion devices and fluid warmers.

Surgical Instruments

Surgical instruments are hand-held tools or implements used by clinicians for the performance of surgical tasks. A vast assortment of instruments can be found in an operating suite. Scalpels, forceps, scissors, retractors, and clamps are used extensively. The nature of certain surgical procedures requires a more specialized set of instruments. For example, bone saws, files, drills (Figure 89-5), and mallets are commonly utilized in orthopedic surgery. Surgical instruments are generally made of carbon steel, stainless steel, aluminum, or titanium, and are available in a range of sizes.

Electrosurgical Units

The electrosurgical unit, or Bovie, is a surgical device used to incise tissue, destroy tissue through desiccation, and to control bleeding (hemostasis) by causing the coagulation of blood. This is accomplished with a high-powered and high-frequency generator that produces a radiofrequency (RF) spark between a probe and the surgical site that causes localized heating and damage to the tissue (Gerhard GC, 1988). An electrosurgical generator (Figure 89-6) operates in two modes. In the monopolar mode, an active electrode concentrates the current to the surgical site and a dispersive (return) electrode channels the current away from the patient. In the bipolar mode, both the active and return electrodes are located at the surgical site.

Defibrillators

A defibrillator is a medical device that is used to deliver an electrical shock to the heart (Tacker, 1988). The shock is intended to correct irregular electrical activity of the heart and to establish an organized rhythm. A shock of adequate power and duration will cause the cells of the heart to simultaneously repolarize and allow a normal rhythm to return. The defibrillator uses a capacitor to store the required energy, measured in joules (i.e., watts per second), to deliver the shock. A DC power supply charges the capacitor to the selected energy level.

Electrodes are used to deliver the electrical shock to the patient. Electrode types include reusable paddles and adhesive electrodes. External defibrillation is applied to the chest of the patient with external electrodes or paddles. An internal paddle set is used when defibrillation is delivered directly to the heart. Factors governing the set-up and performance of a defibrillator include patient impedance, energy waveform shape, and electrode type and placement.

Most defibrillators are designed with technology to monitor the patient's ECG signal and allow for synchronized cardioversion. Synchronized cardioversion is the delivery of energy to the heart during ventricular depolarization, or upon the detection of the QRS

Figure 89-5 Surgical drill.

Figure 89-6 Aspen Labs MF 380 electro-surgical unit.

complex. This feature serves to protect the patient by preventing the inadvertent delivery of energy during the ventricular refractory period.

Temperature Regulation Devices

Temperature monitoring and regulation are crucial to ensure the safety of a surgical patient (Vaughan, 1988). Although heating and air conditioning controls in the operating room help to maintain a safe surgical environment, a patient is at risk of suffering from the effects of hyperthermia, and more commonly, hypothermia. Heat loss can be attributed to contact with conductive surfaces, exposed body cavities, cold irrigation solutions, and convective heat loss due to the considerable flow of air in operating suites. In addition, the effects of anesthesia can impair the body's natural mechanisms for maintaining proper temperature.

Several methods are employed to equalize a patient's body temperature. Blankets, sheets, and clothing are common methods of preventing heat loss. A blanket warmer is also utilized to prevent hypothermia by delivering warmed air to an inflatable blanket surrounding the patient. A hyper-hypothermia unit circulates heated or cooled water through a blanket, to raise or lower a patient's temperature. A fluid warmer is a device used for warming intravenous or irrigation fluids prior to contact with the patient.

Headlamps

Headlamps are used to supplement the facility lights in the surgical field. The headlamp apparatus, worn by the clinician, is connected to a light source by a fiber-optic cable. This versatile source of light is particularly useful when overhead lights are insufficient or obstructed.

Tourniquets

A tourniquet is a surgical device that is used primarily to temporarily occlude blood flow to a part of the body and to obtain a nearly bloodless operative field. A pneumatic tourniquet uses pressurized air to restrict blood flow and comprise an inflatable cuff, connective tubing, pressure source, pressure regulator, and a pressure display. Tourniquets are commonly used in amputations and various other orthopedic surgical procedures (see Figure 89-7).

Specialized Operating Room Technologies

Lasers

A laser is a device that directs an intense beam of radiation to the surgical site to cut, coagulate, or vaporize tissue (Powers, 1988; Judy, 1995). The major components of a laser are the lasing material, mirrors, a cooling system, an optical or electrical pump source, and a

Figure 89-7 Zimmer ATS automated tourniquet system.

delivery system. The lasing material fixes the output wavelength of the laser and primarily comprises a gas-filled tubular cavity (gas) or a solid-state medium. Lasers with differing lasing material, wavelengths, beam shapes, and guidance methods, are used in the operating room for various physiological effects. Four laser types that are typically used in the operating room to coagulate, ablate, or remove soft tissue are carbon dioxide (CO₂), argon ion (Ar-ion), neodymium-yttrium-aluminum-garnet (Nd:YAG), and gallium-aluminum arsenide (GaAlAs).

Robotics

The use of robotics has provided extensive benefits to many industries, and the medical field is no exception. Specifically, surgery is a field wherein the application of robotics can lead to advantages in providing health care. The inexhaustibility, repeatability, and precision of robotics are favorable in surgery.

Imaging Technologies

Body organs, structures, and tissues are studied using imaging techniques (Siedband, 1992). Several technologies are available to the clinician. Hard-tissue imaging is done using X-rays. Soft-tissue contrast and functional information cannot be sought using X-rays. There are many techniques, including computed tomography and magnetic resonance imaging, that are effective in fairly accurate determination of damaged cells or soft tissue.

X-rays

Radiography utilized electromagnetic waves to produce two-dimensional images of anatomy, captured on a photographic film. The intensity of the image on the film is determined by the intensity of the rays emerging from the anatomy. Tissues with different densities will exhibit varying degrees of X-ray absorption. This is the most common form of imaging technique used in clinical practice.

Angiography

Angiography is a radiographic technique where a radio-opaque (i.e., visible on an X-ray) contrast material is injected into a blood vessel for the purpose of identifying its anatomy on X-ray. This technique is used to image arteries in the brain, heart, kidneys, gastrointestinal tract, aorta, neck (carotids), chest, limb, and pulmonary circuit.

Fluoroscopy

Fluoroscopy is a form of diagnostic radiology that enables the radiologist, with the aid of a contrast agent, to visualize an organ or the area of concern in motion, via X-ray. This contrast agent allows the image to be viewed clearly on a television monitor or screen. Contrast agents, also known as “contrast media,” can be introduced into the body by injection, swallowing, or enema.

Computed Tomography

Computed tomography is a diagnostic technique that uses X-rays to acquire detailed information of soft tissue structures, muscles, bones, and organs. It uses an X-ray source that revolves around the object to be imaged. The detector captures the rays (raw data) that penetrate through the organs. The raw information is processed and reconstructed using a computer algorithm to form images. The images are in the form of cross-sectional slices. This technology is particularly useful for producing images of the brain.

MRI

Magnetic Resonance Imaging (MRI) is a noninvasive method of imaging structures and soft tissues inside the body. MRI imaging is very detailed and provides a high degree of diagnostic accuracy, as compared to other modes of imaging. It is based on the principle that hydrogen nuclei in a strong magnetic field absorb pulses of radiofrequency energy and emit them as radio waves, which can be reconstructed into computerized images. The images produced are of a high-quality and give a good indication of the properties of internal body parts. Magnetic resonance imaging is widely utilized by many surgical specialties. It is particularly valuable for imaging soft tissue, the brain and spinal cord, joints, and the abdomen.

MRA

Magnetic Resonance Angiography (MRA) is a noninvasive method of vascular imaging and determination of internal anatomy without injection of contrast media or radiation exposure. The technique is used especially in cerebral angiography, the radiography of the vascular system of the brain, as well as for studies of other vascular structures.

Ultrasound

Ultrasound imaging is technique in which high-frequency sound waves are reflected from internal organs, and the echo pattern is converted into a two-dimensional picture of the structures beneath the transducer.

Minimally Invasive Surgical Devices

For many surgical procedures, the method of choice has shifted from traditional open surgery to the use of less-invasive means. Minimally invasive surgery is performed with the aid of a viewing scope and specially designed surgical instruments (Garrett HMS, 1994). The scope allows the surgeon to perform major surgery through several tiny openings without making a large incision. These minimally invasive alternatives usually result in decreased pain, scarring, and recovery time for the patient, as well as reduced health care costs.

Endoscopy is an examination of the interior organs and body cavities, through a natural body opening or a surgical incision, using a light and a rigid or flexible viewing instrument called an endoscope. The viewing component of an endoscope is made up of hundreds of light-transmitting glass fibers bundled tightly together.

Laparoscopy has become a common surgical technique in the operating room (Brooks, 1994). This procedure is the examination of the interior of the abdomen with a slender endoscope, called a laparoscope. The laparoscope is inserted through an incision in the abdominal wall in order to perform surgery. Laparoscopic techniques are performed to remove gall bladders, to perform antireflux operations on the esophagus, and to remove organs such as the adrenal glands. Although minimally invasive surgery is beneficial for the patient, it is technologically more demanding than traditional surgery. Special training is required for clinicians, and the associated medical technology is more advanced. A laparoscopic procedure is usually performed with a mobile cart that is outfitted with equipment for visualization, instruments for exposure and manipulation, and equipment and instruments for cutting and coagulation.

The equipment for viewing internal tissues and organs include a light source with fiber-optics to transmit the light, a high-resolution camera that can withstand sterilization, a video processor, a high-resolution monitor(s), a video recorder, and a printer. Several devices are employed for exposure and manipulation in laparoscopic procedures. Trocars are sharp-pointed surgical instruments, used with a cannula to puncture a body cavity and to provide intra-abdominal access. A high-flow carbon dioxide (CO₂) insufflator is used to expand the abdominal cavity, to make internal organs more accessible. Graspers are devices, generally with two movable and serrated jaws, that are used to grasp and retract organs (Figure 89-8). Figure 89-9 shows an endoscopic instrument for applying clips. Irrigators (or aspirators) are also commonly used. Instruments used for cutting and coagulation in laparoscopic procedures include microscissors, electrocoagulating dissectors and graspers, heater probes, and lasers.

Heart-Lung Machines (Bypass)

A heart-lung machine (Figure 89-10) is an apparatus that does the work both of the heart (i.e., pumps blood) and the lungs (i.e., oxygenates the blood) during, for example, open-heart surgery (Galletti and Colton, 1995). The basic function of the machine is to oxygenate the body's venous supply of blood and then to pump it back into the arterial system. Blood returning to the heart is diverted through the machine before returning it to the arterial circulation. Some of the more important components of these machines

Figure 89-8 Endoscopic instrument: Autosuture Endo Babcock graspers.

Figure 89-9 Endoscopic instrument: Autosuture Endoclip applicator.

include pumps, oxygenators, temperature regulators, and filters. The heart-lung machine also provides intracardiac suction, filtration, and temperature control.

Transesophageal Echocardiogram

The transesophageal echocardiogram is a device that utilizes ultrasound technology for imaging cardiovascular anatomy and physiology (Schluter and Hanrath, 1984). This device uses an ultrasound probe that is inserted in the esophagus and stomach to image the heart and its associated blood vessels. The internal perspective avoids the interference from the anatomy of the chest encountered with external echocardiograms. Because the esophagus is located just behind the heart this specialized view is clear. The transesophageal echocardiogram uses the same sound-wave technology as a regular echocardiogram. The ultrasound probe emits sound waves of a certain frequency upon the object to be imaged, and the return wave frequency is detected by a transducer. The characteristics of the structure are determined by analyzing the return frequency, and the signals are converted into computerized images.

Transesophageal echocardiograms are frequently used to monitor the heart during surgery. Other common uses include searching for an abnormality in the heart or major blood

Figure 89-10 Stockert-Shiley heart-lung machine under laboratory testing.

vessels that could be responsible for causing a stroke; looking for infections on the heart valves; and evaluating the aorta for a tear in its wall.

Cell Savers

A cell saver is a device that collects and returns a patient's blood that otherwise would be lost during a surgical procedure. This process is referred to as "auto transfusion." The cell saver receives salvaged blood that has been suctioned from the surgical site. The blood passes through filters to remove surgical and cellular debris. Centrifuge technology is employed to separate the heavier oxygen-carrying red blood cells from the other components of the blood. The red blood cells are processed and stored for auto transfusion.

Pacers and Pacemakers

A pacemaker is an electrical pulse generator designed to support the electrical activity of the heart (Greatbatch and Seligman, 1988). A pacemaker can be implanted within a patient or used externally. External temporary pacemakers are commonly used in cardiovascular procedures to treat heart conditions such as bradycardia, atrial and/or ventricular arrhythmias, and cardiac arrest.

The basic pacemaker comprises a pulse generator, a programmer, and a lead. The pulse generator consists of the power source and circuitry, which senses the heart's electrical activity and generates the output. The programmer allows the clinician to adjust pacing variables such as pulse rate, amplitude, duration, and the sensitivity of pulse detection. The lead is an insulated wire that carries the stimulus from the pacemaker to the heart and delivers an ECG signal back to the pacemaker.

Ventricular Assist Devices

The primary aim of a ventricular assist device (VAD) is circulation support. When the myocardium is damaged, the heart is unable to maintain the required cardiac output and blood pressure to maintain blood flow. A VAD is implemented to relieve the workload of the myocardium. Another use of the VAD is ventricular assistance. Patients with heart failure, which can be reversed if the heart is given sufficient time to recover, are candidates for a VAD. Using a VAD is also common after patients undergo cardiopulmonary bypass or any other traumatic heart surgery. A VAD can assist in the recovery of the right or left ventricle (RVAD or LVAD) or both ventricles (BIVAD). An LVAD diverts blood from either the left atrium or left ventricle, sends the blood through a pump, and then returns the blood to the aorta. The RVAD operates in the same manner, with the blood diverted from the right atrium and returned into the pulmonary artery.

Microscopes

Due to the spread of microsurgical procedures through the various surgical disciplines, the surgical microscope has become a valuable tool in the operating room. Microscopes are used to provide magnification and illumination in order to view objects during minute and intricate surgeries. These devices are generally employed when performing procedures, such as neurosurgery, where structures are often very small and can not be viewed clearly with the naked eye. Surgical microscopes generally contain binocular lenses, light sources, optic fiber cables, and focusing mechanisms. Surgical microscopes must be equipped with a mounting or support system in order to be utilized in the surgical field. A variety of support systems are available, including mobile floor stands and ceiling mounts.

Safety in the Operating Room

The hazards associated with medical devices, clinical processes, and human error are of primary concern to the clinical engineer (see Chapter 55). A prevalence of medical equipment and staff in the OR, along with the vulnerability of the surgical patient, creates an environment that requires additional precautions. Potential hazards associated with operating room devices and technologies are vast and can be encountered in many forms. Medical equipment, for example, can pose electrical and/or mechanical hazards to patients and staff. A patient whose natural resistance to current flow has been compromised (perhaps due to an invasive connection to a medical device) is particularly vulnerable to electrical hazards. Devices that are mechanical in nature, such as transport beds and surgical tables, also pose a risk to patients and staff if they are not used and maintained properly. It is a responsibility of the clinical engineering department to implement a program to ensure medical device safety and to manage risk. The program must include the preventive maintenance and inspection of medical devices and systems. It also must conform to codes standards set forth by regulatory agencies such as NFPA, Underwriters Laboratories (UL), Occupation Safety and Health Act (OSHA), and the Joint Commission on Accreditation of Healthcare Organizations (JCAHO).

Other hazards associated with technology in the operating room include environmental hazards, such as the spread of infection due to poor filtration of operating room air; biological hazards, resulting from poor sterilization practices; and radiation hazards from diagnostic machines and therapeutic devices that release radiation (Bronzino, 1992).

A lack of knowledge and communication within the clinical staff significantly increases the likelihood of injuries in the operating room. Familiarity with medical devices, technical processes, and awareness of emergency procedures are key factors in avoiding injury. To meet these requirements, a clinical engineer must provide, or participate in, the in-servicing of new equipment, continual user training, and incident reporting and evaluation.

Adequate preparation requires that the medical staff be properly trained to respond to the following emergencies (see Chapter 116):

- External (community) disaster
- Fire

- Facility-system failure (e.g., power, medical gases, communication systems, elevators, sewer, steam supply, water loss or leak, or HVAC)
- Hazardous-material contamination (e.g., chemical, biohazard, or radiation)
- Infection control hazard

Clinical Engineering Roles

Clinical engineering is the application of technology to improve the quality of health care in health care facilities. It is the responsibility of a clinical engineer to apply engineering principles to understand, develop, control, and maintain medical technologies, systems, and processes. Ensuring the safety of patients and staff is also at the core of a clinical engineer's responsibilities. The role of clinical engineering departments can differ among institutions of varying resources and services. Some clinical engineering departments have an active role in the application of technology for patient care, while others are mainly a "fix-it" shop. Smaller institutions tend to have a centralized clinical engineering department that services the entire facility. On the other hand, larger institutions might allocate groups to specific departments within the hospital.

The operating room is particularly challenging to a clinical engineer. It is an area of abundant and complex technologies. In order to provide proper support to the operating room, the engineer must understand surgical processes and terminology, in addition to providing technological expertise. Ethics and professionalism are also vital characteristics in this field. Members of a clinical engineering department must be conscious of their impact on the patient care process and overall safety in the operating room.

The evaluation and introduction of new technology is a major function of a clinical engineer. The process of medical equipment procurement includes identification of equipment needs, selecting the equipment specifications and vendor, demonstrating the equipment to the users, purchasing the equipment, preparing it for use, staff training, and installation. Medical devices and technologies are provided to promote quality patient care, yet ensure cost effectiveness. Hospitals generally operate with limited funds with a growing demand for medical services. Therefore, it is vital for clinical engineers to plan investments in medical technology carefully and to maintain the equipment following procurement. The clinical engineer also must be mindful of the codes and standards that regulatory agencies have applied to health care technology.

The operating room's dependency on technology for patient care demands that medical equipment be reliable and available. The clinical engineer is responsible for ensuring that equipment is properly maintained. Preventative maintenance and scheduled inspections are necessary to minimize malfunctions, to verify functionality, and to prevent device-related injuries. Spare devices and replacement parts should be maintained for all vital equipment.

Inventory records must be kept in order, to manage the assets of the operating room. A computer database is an essential tool for managing data such as equipment inventories, parts inventories, and inspection schedules. A device's individual performance and repair histories also should be stored for future reference. Other responsibilities of a clinical engineer can include device design, project management, budgeting, staff training, incident investigation, and facility design.

Conclusion

The operating room is a complex department that serves an essential role within a health care facility. This environment comprises a wide range of clinical professionals, medical technologies, and complex systems. The clinical engineer, as a technical expert, is essential to the efficiency and safety of the health care facility. To support the OR effectively, the clinical engineer must maintain a thorough knowledge of medical devices, clinical practices and procedures, facility systems, and safety guidelines.

To excel as a clinical engineer or biomedical engineering technician supporting the use of equipment in anesthesia requires equally strong understanding of both the clinical and technological components of the job. This is an important distinction that anyone must face when involved with anesthesia. Physiology and technology meet—the two cannot be separated. If you know the technology well but have less than able comprehension of medical terminology, human anatomy, and physiology, you will have difficulty making efficient decisions to correct a problem in the middle of surgery or to choose the best technology to be used for the next 15 years. This chapter is primarily dedicated to existing and present technology. Future machines are not discussed in detail, as it would be purely speculation as to what might work. Most discussions are limited to principles and not specific detail.

This chapter is best introduced and summarized with a case report. Events similar to the one described below have happened, and will happen, at most any institution. Suppose that in the middle of a total hip replacement in an operating room (OR) where ultraviolet (UV) lights and laminar flow ventilation systems are used to keep infection rates to a minimum, the clinical engineer (CE) is asked to diagnose a large leak that has developed in the breathing circuit during the case. The resident and attending physicians are concerned about the course of events, and the CE can feel the tension upon entering the room. Alarms are sounding, and it appears that the doctors are having a difficult time ventilating the patient. The physiological monitor is indicating poor oxygen saturation; it tells the CE that the capnogram shows a poor waveform. The ventilator is flashing a number of alarms. The attending physician wants a new anesthesia machine, now. The CE is told that the patient is paralyzed and that they will use an Ambu bag (i.e., a manually operated resuscitator) while the CE gets that broken machine out of the room.

The CE wants to perform a couple of tests on the machine but is concerned that asking for the time to do it will add more tension. Wanting to solve the problem as fast as possible, the CE does as told. Quickly, the CE is out of the OR and off to find another machine. Meanwhile, they disconnect the patient from the machine, start manual ventilation, and rearranging things in the operating room so that the CE can wheel the large device out and roll in another in its place. The CE returns and leaves the new machine just outside of the room, helps the physicians move all items and drugs from the existing machine, disconnects patient monitoring, gas-supply hoses, and electrical connections. The CE wheels the machine out of the room (careful not to touch sterile tables and drapes, or else there would be even more upset people), and moves the new machine in. With great care, things are reconnected, and every detail is put back in its place. The new machine and then the ventilator are turned on. The very same problem is still there. The bellows do not fill properly, even with a fresh gas-flow rate of 10 lpm. Tension is building. The CE has done everything asked of him, and there is nothing else that he can think of. The physicians are growing even more upset. Not wanting to be in the way, the CE decides that it is time to leave.

Back in the clinical engineering department, the CE finds a co-worker and discusses the recent occurrence. The co-worker convinces the CE that they both should go to the OR. The first machine is still in the hallway. They plug it in and turn on the oxygen cylinder. A quick breathing circuit leak test and a functional ventilator test indicate that nothing is wrong with that machine. In the room, everyone is near an uproar because they

cannot ventilate adequately. The co-worker asks the physicians to turn off the ventilator and to manually ventilate the patient. They must use the oxygen-flush key just to keep enough volume in the breathing circuit. The CE notices that the breathing circuit bag is actually collapsing between breaths. There is something pulling vacuum in the breathing circuit. The CE knows that there is now a different scavenger connected, so that cannot be the problem. Remembering the nasogastric suction catheter (used to empty the esophagus and stomach contents), the co-worker asks for it to be pulled out a little. The physician pulls back on the tube, and everything comes back to normal. The CE is amazed that a doctor missed the cause of such a leak.

Humans make mistakes. Safety is the responsibility of everyone involved. There must be redundancies to help prevent a number of events that would result in an adverse outcome. Multiple factors played into this case. Tunnel vision, a lack of comprehension in the application of technology, simply following orders without thinking or communicating, striving to be the one to solve a problem, and not seeking help from others all contributed to the confusion of both clinical and technical staff while putting the patient at greater risk and increasing the possibility for serious infection.

What Is Anesthesia?

Pre-Operative Assessment and Plan

Anesthesia is more than the manual labor and technology involved in relieving patients of pain that they would otherwise endure during surgery. To determine whether a patient is ready to undergo anesthesia, anesthesiologists must assess a patient's current state with a physical examination, evaluate lab results and other relevant tests (e.g., EKG and renal and pulmonary function) and medical history while taking into consideration personal preferences, and even religious beliefs, on occasion. A perioperative management plan must be developed. The physician and patient will discuss options and risks of local, regional, and general anesthesia as well as backup plans in case unexpected events occur. In doing so, they must take into account any risks to which the patient will be subject. A neonate with poor lung function, a healthy adult, and a hemodynamically unstable elderly patient all pose different challenges. In anticipating what could happen during the surgical procedure and what the level of difficulty any one individual patient may be, the anesthesiologist must decide among many things, such as level of monitoring, vascular access (replenish fluids and sample blood gases) and airway management.

Amnesia and Analgesia

Anesthesia is an induced, controlled state combining amnesia and analgesia during surgery, obstetric, therapeutic, and diagnostic procedures. Overall, the safest approach is to leave the patient as self-sufficient as possible. Under proper management, a patient who is spontaneously ventilating (breathing unassisted) is inherently at less risk than a patient requiring mechanical, or assisted, ventilation. For minor procedures, local anesthesia, as

with the use of peripheral nerve blocks, is performed by an anesthesiologist and monitored by less-trained personnel during the procedure. This is known as monitored anesthesia care (MAC) and often involves nurses without extensive anesthesia training. For more invasive cases, spinal and epidurals (regional blocks), combined with sedation, can be used to perform many surgical procedures. There are significant risks involved. Regional anesthesia frequently requires the immediate availability of appropriately trained personnel and general anesthesia equipment as backup. Epidurals can be used for surgical needs and postoperative pain management.

Conscious sedation is often used in intensive care units. It can be used as a means to restrict patient movement and to aid relief in highly stressful times. It is also used for imaging child patients or irritated individuals. There is a hazy, but fine, line (often misunderstood) between where conscious sedation ends and general anesthesia begins. Anesthesiologists tend to have a clear understanding of the boundaries but others who are not as experienced in the practice might not.

General anesthesia (GA) affects the entire body, rather than any one specific area. GA shuts down the body's reactions to noxious stimuli most often also involving paralysis. The minimum alveolar concentration (also referred to as MAC) is the minimum anesthetic agent to prevent 50% of the population from moving because of noxious stimuli (i.e., incision). By definition, one MAC is not enough to treat patients, as half would react to an incision. A value of 1.3 MAC will prevent most any patient from moving. One MAC varies by intravenous drug and inhalation agent. It is a measuring tool to standardize comparisons. For example, one MAC is accomplished at 1.68% of the volatile liquid anesthetic ethrane and at 1.15% of the anesthetic forane. Because GA affects the entire body, there is total loss of consciousness and the ability to communicate, thus requiring physiological monitoring to best determine the patient's condition. During GA, the patient is often paralyzed to the point where autonomic control of the diaphragm is shut down, thus requiring the use of positive-pressure (mechanical) ventilation and related monitoring.

Critical Care

Many anesthesia departments are deeply rooted and involved in the day-to-day operations of intensive care units (ICUs). Training in anesthesia is a solid foundation for management of critically ill patients (Stoeling and Miller, 1994). Patient care during surgery is, in many ways, similar to that of other critical care areas, but changes happen in terms of minutes or hours, versus days or weeks. Because of their specialty and experience, anesthesiologists must understand intravenous administration of rapidly acting drugs, fluids, and volume control. Critical care calls for in-depth knowledge of mechanical ventilation, airway management, and cardiovascular monitoring, including invasive pressure lines of hemodynamically unstable patients. Anesthesiologists are also responsible for cardiac and pulmonary resuscitation (code response) in the ORs and ICUs.

Pain Management

Anesthesia departments are also responsible for pain management during diagnostic, therapeutic, and obstetric procedures. Pain units that are staffed by anesthesiologists diagnose and treat painful syndromes when patients suffer from chronic issues. Obstetric floors often have anesthesiologists present, to help reduce the pain involved with labor and delivery.

Considering all of this, do not overestimate anesthesiologists. They are not superhuman. No individual will master all of these specialties. As a clinical engineer or biomedical equipment technician (BMET) supporting the needs of the department and its staff, it helps to understand the breadth of responsibilities and expectations of the physicians as a whole.

Where Is Anesthesia Performed?

Operating rooms, treatment rooms, and intervention radiology suites are beginning to look more similar than ever. Historical functions of the different areas and physician specialties are blending, making formerly clear lines quite hazy. Patient flow through the hospital's multifaceted care units must be carefully planned. Preparing and recovering a surgical day-care patient (rather than one from general surgery) will put significantly different demands on support systems and staffing. The hospital cannot afford bottlenecks that result with unnecessary delays in surgical, imaging, or other expensive care areas.

For various reasons, doctors and patients alike express interest in providing anesthesia at remote locations (out of the operating room) of the hospital. This poses significant risks and unique challenges in planning, supporting, and actually meeting the demand. These remote sites most often were not designed with anesthetizing-location-facility requirements in mind. Details of facility criteria are discussed elsewhere in this handbook (see Smith et al., Chapter 89). Reliable supplies of oxygen and suction, along with adequate electrical power and lighting, are key components. The lack of any of these can negate further discussion. If facility requirements are met, but physical space is an issue, the anesthesiologist, machine, and supplies are often crowded into an uncomfortable corner. From a user's perspective, they are away from the space to which they have grown accustomed. People must be extra vigilant when they are out of their normal element, as supplies and other things are not where they are expected to be. More importantly, support personnel are not immediately available to help in emergencies, as in they are in the operating room. One example is the need of imaging pediatric patients. Small children tend not to stay still enough for adequate results, and therefore need sedation. Unless properly planned, pediatric supplies are not commonly found throughout the hospital. Delays in procuring critical care items could lead to disastrous results.

The special needs of magnetic resonance imaging (MRI) and radiation oncology (e.g., proton beam accelerators) present unique challenges to all involved in their use. The most significant are magnets and invisible forces. Both technologies involve strong forces that cannot be seen, and catastrophic events can result if mistakes occur. Specialized equipment is needed, to detect the energy field generated by both types of devices.

MRI requires highly specialized equipment: Nonferrous magnetic materials can be used, CRTs are a problem, radiofrequency (RF) sensitive environment, physiological monitors are less than optimum, the same level of monitoring is simply not available, application of MRI is expanding and it is being used more frequently during surgery. Radiation oncology requires leaving anesthetized patients by themselves, which is not something that people take lightly. Anesthesiologists still need to be able to monitor the patient and machine while they are out of the room

Safety Concerns

The single most significant difference in supporting anesthesia technology, as distinguished from any other clinical engineering function, is that there is a susceptible patient connected to life-support equipment, and they are given medications that bring them relatively close to death. Anesthesiologists are keenly aware of this. As a whole, stress levels of people in operating rooms are exacerbated because the patient has undergone two forms of injury when on an OR table. They have suffered the initial illness or trauma that has brought them to the OR, and they must undergo the trauma of the surgical procedure itself. It can be difficult to believe that the patient often must experience additional trauma in order to get better.

Patient safety is a team effort. No single department bears the responsibility for overall patient safety. Everyone must evaluate their individual responsibilities and must look for ways to prevent and improve their environment, to prevent mishaps from occurring. One example of a relatively simple sounding task, but often complicated by various factors for the OR team, is patient positioning. A number of injuries have occurred because of positioning. Different departments must take into account their own prospective needs. Surgeons must have access to certain areas for sterile prep and the surgical site. Nurses must make sure that the items for which they are responsible are accessible and do not cause potential pressure points, while anesthesiologists are looking out for potential nerve injuries. Because the patient is unconscious, he is unable to tell them that the position is uncomfortable, and staying that way for six hours can hurt.

Anesthesia safety is frequently compared to flying an airplane. On airplanes, most of the problems (and, therefore, most hazards) are associated with take-off and landing. In anesthesia, this is equivalent to induction and emergence. Both have multiple systems working in unison to maintain function. On a commercial plane, fuel is delivered precisely to engines that are attached via structural members to a fuselage, with a crew using radiofrequency communication and a global positioning system to move the plane from one location to another. During anesthesia, oxygen is mixed carefully with an inhaled anesthetic agent and delivered through a breathing circuit driven by a ventilator, controlled by a physician who watches a display to monitor electrical and physical changes in a patient who cannot communicate. As long as things are going well, everything appears to be relatively simple.

Unfortunately, things do not always go as planned. A number of factors can contribute to undesired events during anesthesia, including noise, fatigue, and boredom (Weinger and Englund, 1990). Studies have shown that anesthesiologists can be idle 40%–70% of the time during a surgical procedure (Drui et al., 1973; Boquet et al., 1980), which could further affect their vigilance at their primary responsibility of monitoring the patient, procedure, and equipment. When something out of the ordinary occurs and takes anesthesiologists off their planned course, it can lead to moments of high activity, where many things must be accomplished in little time, potentially in a state of concern. These periods are often associated with high task density, where people average less time on individual tasks in contrast with the time spent during less busy periods (Herndon et al., 1991). In both aviation and anesthesia, there are lengthy, intensive training periods and highly educated and skilled personnel. Each field relies on a person who has a widely varying workload, to maintain order. It does not take much time for one or two additional missed warning signs to result with significant demands on the individual at the controls. For a pilot or an anesthesiologist, an uneventful day is a good day. No one likes unpleasant surprises on an airplane or in anesthesia.

Redundant systems help to prevent surprises. Studies in the aviation industry show that adverse outcomes frequently happen when a number of undetected smaller events occur, involving different factors (e.g., human error, equipment failure, and supply mishaps) cumulating in an undesired result (Billings and Reynard, 1984). There always should be additional resources for people to turn to for help. This can be difficult for some, because they may feel that asking for help shows a weakness and that they should be able to figure it out on their own, lest they be seen as less than fully capable. Patient care environments must try to foster a setting in which looking for help when an individual is not fully comfortable with a condition is a perfectly respectable option and not cause for punitive action. Solutions can be relatively simple but not visible when an individual is fixated on something else. Another viewpoint might be all that is needed. Physicians frequently have enough to worry about and might not always see the solution; this state of affairs can be more prevalent at teaching institutions. Clinical engineers can back physicians up by understanding the demands placed on them and on the clinical environment.

To minimize the possibility of equipment failures during use, the aviation industry implemented a preflight inspection. Similarly, those who are concerned with anesthesia safety developed the United States Food and Drug Administration (FDA) Anesthesia Apparatus Check-out Recommendations (FDA, 1993). A team of people of varied backgrounds and interests created the FDA procedure. When followed correctly, this comprehensive procedure can identify most any problem. Although it is a simple procedure, it does require the user to know proper technique. It can be simple to make a mistake (e.g., negative pressure leak test with the machine turned on) that results in false positives or negatives. Most anyone with a reasonable understanding of an anesthesia machine can perform the checkout. A technician or engineer with more in-depth knowledge of the components that are actually being tested can use it as a useful troubleshooting tool to easily identify system failures within the machine.

The aviation industry has used simulators for years. Their use is expanding medicine to put physicians in stressful situations without putting patients at risk. People need to be

taught crisis management. One needs to conceptualize and understand how to work in a team when encountering stressful and challenging situations. The human mind does not function rationally when in a panic.

Safety at off-site locations is worth noting. A number of undesired events have prompted review of office-based anesthesia. The associated risk versus cost is an example of the many challenges faced in health care, particularly at large teaching hospitals. In an effort to stay price-competitive with the entire medical industry, procedures are being performed out of the operating room and in doctors' offices. No one should ignore the fact that infrequent events with potentially catastrophic outcomes do happen. Key components can be as simple as proper and adequate supplies, additional personnel, and available telephones. Other components depend on the procedure and level of anesthesia performed. Even though some procedures appear to be relatively simple, the requirements for anesthesia can call for a machine to be present at all times. The emergent need for mechanical ventilation and use of volatile agents is quite possible. These machines might be underutilized, but they are subject to greater wear because they are moved more frequently than machines based in the operating room.

There are supply concerns, as well. Additional stock is not as readily available when users are not in the main supply area, which normally is the operating room. If items stored differently, individuals are out of their normal surrounding, and this contributes to disorientation and difficulty locating the items. Delays in supplies can have catastrophic results, as well. If the correct endotracheal tube is not readily available, minutes might as well be hours when there is a problem with an airway.

Infrastructure

Smith et al. described facilities' infrastructural needs (see Chapter 89). Much of an OR's evolution has involved the application of anesthesia and some of its historical limitations. Conductive flooring, other electrostatic discharge protection, and explosion-proof electrical connections were directly and indirectly employed because of former anesthetic technology. Currently, there is ongoing debate about the continued use of the isolated power supply (IPS) in new construction. The use of ground fault interrupts (GFI) meets code requirements for wet locations at a lower cost than isolated power. Some facilities elect to continue with the more expensive option because it does not shut off power to an outlet at the first fault. If their application is poorly understood, GFIs could be hazardous when life-support equipment such as anesthesia or cardiopulmonary bypass machines is used. Shutting of life support equipment when one plugs a faulty device into an outlet on the same circuit is not a wise alternative.

Following are a number of other systems that are needed, to support specific needs for anesthesia:

- Immediate access to the hospital's pharmacy and a means to control narcotics with potentially high throughput for busy centers
- A well-organized means to purchase, receive, and stock single-use supplies
- Facilities and associated documentation to reprocess, decontaminate, and sterilize multiple-use devices
- Centralized storage of equipment that is not used every day but must be available
- An area for preadmissions testing
- Space for an interview and simple testing

Patients and physicians need to interact preoperatively to assess and plan the anesthesia. This may also be done in general-care areas if the patient has been admitted in the hospital.

Induction (or holding) rooms offer a number advantages and disadvantages. They require more patient movement and additional equipment but can reduce turnover time and can increase throughput. Primarily, they provide a location to help set up lines and epidurals without occupying time in the operating room itself. They are no longer true induction rooms, as anesthesia is not induced in them, but they are helpful prep areas.

In the ORs, anesthesia machines must connect to existing infrastructure for gas supplies. It is useful to have standardized connections so that machines can be used in any location with adequate infrastructure. Individual surgical anesthetizing teams might have varying needs and preferences for machine and monitoring layout, depending on the surgical service that they support. There also are specialized sites like radiation oncology and MRI that will require the machine to be tailored to meet their requirements.

Post-anesthesia care units (PACUs) have established clinical personnel requirements for emerging patients (ASA, 1994). Patients can be unstable; so immediate critical care, airway management, and possibly anesthesia equipment must be available. Their workload varies. At one moment, the space could be used primarily for pre-op holding; at other times, things can be relatively calm. Then, suddenly, three or four cases finish at once. The PACU is an ICU and must have similar monitoring requirements with centralized alarms. It must accommodate varying demands for stretchers used in patient transport.

Airway Management Tools

One of the most critical tasks in caring for the ventilated patient is in securing an airway. If there is not a reliable means of moving gases in and out of the lungs, cardiac resuscitation follows respiratory arrest. Among the many tools available to anesthesiologists, none is more important for airway management than suction. Reliable and adequate sources of oxygen and suction are vital. Anesthesia cannot be performed safely without both. Yankaur catheters are the most typical device used to aspirate airways. Nasal-gastro tubes are used to empty stomach contents that otherwise could interfere with the airway.

Probably the device with which most people are familiar is a facemask. Masks are relatively simple devices that come in numerous sizes, both disposable and reusable. They

can leak if not fitted correctly, and they require a hand or strap to hold them in place. Their greatest drawback is that they do not prevent possible aspiration of stomach contents. They are not the best option for longer cases, and excessive pressure can cause physical injury to the patient.

To use most any other airway management tool requires direct visualization with a laryngoscope. There are standard airway classifications, depending on patient anatomy. Laryngoscopes are available in various configurations to best meet the needs of different airway anatomy. Common blades that are used to obtain direct visualization of the vocal cords are straight, straight with curved tip, or curved (Jackson-Wisconsin, Miller, and MacIntosh, respectively). When patient anatomy or trauma is such that use of a laryngoscope is difficult or impossible, a fiber optic scope is used to help intubate the patient. The two services that most often require these tools are thoracic and plastic surgery. Thoracic teams use them to visualize airways more easily, evaluate tube placement, and aspirate secretions. Reconstructive plastic surgery requires the use of fiber optic scopes, as a significant percentage of these patients have disfigurement or trauma that has altered normal anatomy. Video equipment can help teach their proper use by enabling two people to visualize the same image at once.

Endotracheal (ET) tubes are the most common item used to maintain an airway. They are available in numerous sizes and in cuffed (Figure 90-1) and uncuffed configurations, although cuffed tubes are more common. They have a balloon-like outer section at the distal tip that inflates to seal with the inner walls of the trachea to prevent leaks and inhalation of gastric contents or other secretions. They are nearly always used on adults, and they pose other potential problems if the patient is intubated for periods over 48 hours. Uncuffed tubes do not put pressure on the inside of the trachea that can be more problematic with pediatric patients but can contribute to airway leaks. The most frequent problem associated with intubation is a sore throat from the pressure exerted on the inner tracheal mucosa. There are specialized ET tubes with two lumens used most frequently during lung surgery, enabling ventilation of one lung or both. Because they are in the immediate surgical vicinity, these tubes are subject to greater external forces and, therefore, are often reinforced. Another option is the laryngeal mask airway (LMA). Because of its seal design, its use is limited to ventilation pressures of about 20 cm H₂O, and it does not prevent aspiration of gastric contents. The LMA is most efficient in environments where surgical procedures are generally short, and it is a helpful tool for emergent needs.

Services that pose unique challenges are pediatrics and oral surgery. Children are smaller, potentially making tasks more challenging. In oral surgery, scavenging can be challenging because surgery takes place in the immediate area where gases are flowing.

Anesthesia Machines

Anesthesia machines (see Figure 90-2) are constructed of a number of systems assembled as one device. There are standards developed by the American Society for Testing and Materials (ASTM) (ASTM, 1989) for many of the subassemblies used on or with the machines. Its major systems can be broken down to gas delivery (frequently referred to as the "machine," itself), vaporizer(s), breathing circuit, ventilator (including related monitoring), physiological and CO₂ and agent monitors. One standard does not cover all aspects of the machine; for example, there are standards for machine, ventilator, oxygen monitor, and breathing circuit. Unfortunately, they can be vague and interpreted in different ways, making them somewhat difficult to read and understand.

Gas Supplies

The machine's primary function is to reduce supply-line pressures, mix a number of gases (most typically oxygen, nitrous oxide, and air), and deliver a controlled output to the breathing circuit. Primary gas supplies feed the machine 50 psi. A pressure-relief valve opens above 75 psi in case of infrastructure system failure. Technicians and engineers need to be familiar with a number of pressure-measurement units. The most common are pounds per square inch, millimeter of mercury, and centimeters of water (psi, mmHg, and cmH₂O, respectively). A rough equivalent is that one psi is about 50 mmHg and about 70 cmH₂O. In the same units of measure, an anesthesia machine needs to safely reduce and control gases fed at 3500 cmH₂O and to supply them to the breathing circuit normally operating at about 35 cmH₂O. In other words, the supply pressures are 100 times that of the breathing circuit. Machines are constructed with a high-pressure side and a low-pressure side. The high-pressure side is primarily the supply, and the low-pressure side is any part operating near breathing-circuit pressure.

Figure 90-1 Cuffed endotracheal tube.

Figure 90-2 Anesthesia machine.

There are a number of items with designed incompatibility in anesthesia machines. Pipeline gas-supply connections are available in a few different configurations. The diameter indexing safety system (DISS) is a common configuration. The thread and inner diameters vary to prevent accidental connections to a wrong supply. Virtually all machines use E cylinders as backup supplies. Backup oxygen is vital for patient safety and must always be available. Cylinders use the pin index safety system (PISS) to prevent wrong connections. Holes in cylinders work in conjunction with pins in the yokes. For anesthesia-supply gases (oxygen, nitrous oxide, and air), one pin location is fixed, and the other varies depending on gas type. One inherent weakness in this system is that if the wrong pin pulls out or breaks, it could lead to a misconnection.

Oxygen Pressure Detecting System and Distribution

To detect the presence of oxygen pressure, there is a pressure-controlled, normally off, valve called the "fail safe," which is intended to protect the patient from a hypoxic mixture. Its function is to shut off secondary and tertiary gases in case of oxygen loss. The name is a misnomer because the device does fail. It is ineffective when other gases are delivered in the oxygen pipeline or when flow-control valves or hypoxic mixture interlock systems are out of adjustment. Machines also have a pressure-sensing alarm that indicates when supply pressure has fallen below a threshold to inform the user to take evasive action (e.g., to turn on cylinder supply).

Oxygen-pipeline supply is plumbed to at least five locations at full pressure within the machine. The oxygen-flush valve is always active and capable of delivering 50–65 lpm. It incorporates a safety-pressure relief at about 120 mmHg for catastrophic failures that far exceed normal breathing-circuit pressures. The flush valve is dangerous to the patient in the hands of an uninformed user. Activating the flush for one second will increase the tidal volume delivered by one liter, which is easily enough to cause barotrauma to a susceptible patient. The fail-safe and pressure-sensing alarms, as described above, require line pressure to operate correctly. Flowmeters combined with the flow-control valves feed the oxygen supply to the patient via vaporizer(s) and breathing circuit. They are the interfaces between the high- and low-pressure sides of the machine. Ventilators need a working gas. The United States has standardized on oxygen, but other parts of the world could use air. Auxiliary flow meter and other power outlets are fed from accessory connections.

The anesthesia machine has two limits for the minimum oxygen-flow rate. One is fixed and sets at the absolute minimum deliverable, while the other varies in proportion to the

nitrous oxide flow-rate setting. Most machines are designed for a minimum of 200 ml, but some go as low as 50 ml. This is intended to reduce the possibility of a hypoxic mixture because there is always the minimum patient-uptake requirement supplied. An average adult will metabolize about 2-300 ml/min of oxygen.

Nitrous oxide flow control is linked directly or indirectly to the flow of oxygen, also to prevent delivery of a hypoxic mixture. This introduces significant associated construction costs and complexity. As technology and practice evolve, people are questioning the long-term use of nitrous oxide and wonder whether it still should be made available in all machines. To compensate for potential supply pressure changes that could alter flow settings from one machine to the next connected to a common supply line, some manufacturers use two-stage pressure reduction to minimize the effects.

Gas Mixing

Traditionally constructed (mechanical) machines use a needle valve combined with a rotameter for each supply gas to control flow. The rotameters all feed a common output, thereby regulating gas composition fed to the vaporizers. After mixing with the inhalation agent delivered by the vaporizer, the combined mixture is called the "fresh gas flow" (FGF), delivered at the common gas outlet. Some electronic machines have settings for total gas flow and oxygen percentage that control gas-flow rates independently.

There is a check valve built into the common gas outlet on Datex-Ohmeda machines to prevent breathing-circuit pressures from back-pressurizing the vaporizers. This valve requires a negative pressure, to open and correctly perform a leak test on the low-pressure system. If a positive-pressure test is performed, it will not open this valve, and the machine will not be tested properly. Dräger machines do not have this check valve.

Machine and Space Layout

Much of the machine consists simply of shelf space, essentially a convenient location to store monitoring equipment and supplies needed when performing anesthesia. A working surface and tabletop space is an important location to place medications and other items needed within hands' reach of the physician. There is also a chest of drawers to store supplies and other items needed for use with the machine.

People adjust the layout of most anything they use regularly. They become accustomed to what they have, and grow to like where things are positioned. If the things with which one interfaces change radically, it affects one's comfort level. One is more likely to make mistakes by turning the wrong knob, leading into additional confusion because of rituals and habits of looking for things in one location. Consistency, particularly at large institutions, has its advantages and disadvantages.

The physical space layout and the way the machine is positioned in the room can be significant. If the user is forced, due to an awkward machine orientation, to use their right hand for holding the mask, and their left for manual ventilation, it is very difficult to adapt. To help understand this, one need only try brushing one's teeth with the nondominant hand. It can be done, but would one want a person's life in one's hands when doing it the first few times? The patient's orientation affects access to the endotracheal tube and ease of inspecting lines, leads, and electrodes. The patient could be prepped and draped so that it is very difficult to reach most anything.

Vaporizers

Vaporizers (Figure 90-3) add and control the concentration of volatile inhalation anesthetic agent in the gas delivered to the machine's common gas outlet. In order to understand the way a vaporizer functions, the reader first must be familiar with a few terms and principles of fluid dynamics. A fluid is anything (liquid, gas, or both) that takes the shape of its container. Materials have three phases: Gas, liquid, and solid. Vapor is the gaseous phase of a liquid at room temperature and atmospheric pressure. Pressure, volume, and temperature are related. A gas is fully saturated when it contains the maximum amount of vapor possible without precipitating out to a liquid. If two or more gases are mixed in one container, the total pressure exerted is made up of the sum of partial pressures created by each individual gas.

Partial Pressure

An understanding of partial pressure is required, to support anesthesia technology effectively. Partial pressures are an absolute measurement defining the total number of molecules where percentages are relative to total gas mixture. Partial pressure is used and applied in a number of technologies within anesthesia (e.g., vaporization, ventilation, and respiratory gas monitoring). One example to help clarify the term is dry (versus moist) air. Air is made of 21% oxygen. The remainder is mostly nitrogen and trace gases (negligible partial pressure for this example). Atmospheric pressure is approximately 760 mmHg. On a dry, warm day (98°F or 37°C) of 0% relative humidity, oxygen partial pressure is 21% of 760 (0.21 × 760), or 159.6 mmHg. The remaining pressure must be from nitrogen (760-159.6), or 600.4 mmHg. Then, on the following day, the temperature and atmospheric pressure are the same as the day before, but the relative humidity is 100% (the air is fully saturated with water vapor and cannot contain any more without rain-out). At 37°C, fully saturated water-vapor pressure is 47 mmHg. On the second day, atmospheric pressure contains three gases (nitrogen, oxygen, and water vapor). Oxygen concentration remains constant at 21%, but its partial pressure is a function of the three gases [0.21 × (760-47)] or 149.7 mmHg. The partial pressure of nitrogen is 0.79 × (760-47) mmHg, or 563.3 mmHg.

Because volatile inhalation agents have varying partial pressures that affect concentration output, modern vaporizers are made agent-specific. The most common agents currently in use are forane, ultane and suprane (manufacturer trade names are isoflurane, sevoflurane and desflurane, respectively). Vaporizers are available as either funnel- or key-filled. Funnel-filled vaporizers can be more convenient and reduce the possibility of

Figure 90-3 Vaporizer.

vapor lock when filling, but they are susceptible to being filled with the wrong agent. Key-filled vaporizers are more cumbersome and require use of a filler, but they virtually eliminate the possibility of cross-contamination because the agent is not poured directly into the vaporizer as in the case of funnel-filled units.

Operating Principles

Side-Stream

All of the mixed gas flows through the inside of a side-stream vaporizer. The main stream of this gas (when flowing through a vaporizer it is also known as the “carrier gas”) has a fraction diverted to the wick/sump assembly. The amount of flow of this side-stream diverted to the wick assembly is controlled by the setting on the vaporizer output dial. The higher the output setting, the greater the amount diverted. This side-stream flow becomes fully saturated with anesthetic vapor in the wick assembly and then returns to the main-stream controlling agent concentration output in the fresh gas flow.

Two physical principles cool this style of vaporizer, requiring temperature compensation. Forced convection (flow of gas) and latent heat of vaporization (energy required to vaporize a liquid) cool the vaporizer while in use. Cooling an anesthetic agent reduces its partial pressure, which in turn lowers the vaporizer’s output. To compensate for this cooling, vaporizers incorporate a bimetallic temperature-sensitive diverter that adjusts the amount of flow fed to the side-stream from the main carrier gas. As temperature drops, the side-stream of gas increases to maintain a constant output over varying temperature during normal operation. Side-stream vaporizers, which are relatively simple in design, are the most commonly used and are available for all of the currently used agents, with the exception of Suprane.

Mainstream Injection

Suprane is a volatile agent with high partial pressure that makes it difficult to deliver with a traditional side-stream vaporizer. It can be delivered only using a mainstream injection vaporizer. Suprane vaporizers are heated and pressurized to control more precisely the

environment in which it is stored when in use. Mainstream vaporizers control output by injecting measured amounts of agent directly into the main stream of carrier gas.

Future machines might incorporate new designs that are more closely related to the mainstream vaporizers for other agents. Vaporizers are also used on heart-lung machines to control the anesthetic agent delivered through the oxygenator during cardiopulmonary bypass surgery.

Breathing Circuits

Breathing circuits serve as the interface between patient and machine. Because people breathe in volumetric flow and pressure cycles and anesthesia machines deliver a unidirectional stream of gas (at a specific oxygen concentration and controlled anesthetic agent), an interface between a person and the anesthesia machine is required. Breathing circuits convert the machine’s steady gas output to a flow and pressure cycle that is consonant with the human breathing cycle.

In keeping with the Ideal Gas Law, $PV = nRT$, to maintain a constant baseline pressure, one must also maintain a constant baseline volume. If there is excessive (or a growing) volume in a closed system, pressure will pressure. Respiratory baseline pressure is measured at end-tidal expiration when there is no longer significant flow. This measurement is known as “positive end-tidal expiratory pressure” (PEEP). A second ventilation indicator is “peak inspiratory pressure” (PIP), the maximum pressure attained during the inspiratory cycle.

When a patient is paralyzed to the point where they no longer spontaneously ventilate, positive-pressure ventilation is used. This involves delivering pressurized tidal volumes of gas to the patient’s lungs for oxygen uptake supporting their required metabolism. Under normal circumstances (no leaks), an anesthesia machine’s gas output has two places to go: Patient uptake or its scavenging system.

A primary component of breathing circuits is the tubing and its configuration to the patient. Some breathing circuits rely on high fresh gas flow rates to prevent rebreathing of respiratory gases while others involve absorbent to neutralize expired carbon dioxide. A thorough discussion of all the breathing circuit (open, semi-open, semi-closed, and closed) options is too great for this text. The two most common circuits used in the United States, the Bain Circuit and Circle System, are described below.

Bain Circuit

A Bain Circuit is a semi-open breathing circuit that does not recirculate respiratory gases and relies on high fresh gas flow rates to prevent rebreathing. It is most often used for neonatal and thoracic applications. Its greatest advantages are that it creates little dead space, it is lightweight, and gases can be scavenged easily. The most significant drawbacks to this circuit are that it requires high fresh gas flow (delivering cold dry gases to the patient) and can be cost-prohibitive with costly volatile agents.

Circle System

By far, the most common is the circle system, where respiratory gases move through a housing incorporating unidirectional valves to recirculate gases, minimizing waste and maximizing warmth and humidity in the circuit. The system’s greatest drawback is its level of complexity. However, nearly all anesthesia machines are designed to operate with a circle system.

Carbon Dioxide Absorbers

Recirculating breathing circuit gases require the patient’s expired carbon dioxide to be removed, to prevent hypercarbia. This is accomplished by means of a CO_2 absorbent contained in a housing, called an “absorber.” The breathing circuit absorber must allow the use of both automated (machine ventilator) and manual (breathing circuit bag) ventilation. Most present-day absorbers are stand-alone subassemblies that tie into related functions of the machine. They are modular and can be exchanged easily if needed. They are the union between patient and machine and are where respiratory gases mix with fresh gas flow from the machine. Delivered oxygen concentration is measured in the absorber’s inspiratory limb that is most proximal to the patient and in a relatively safe location where it is unlikely to be damaged or disconnected. One advantage of modern absorbers is that they measure PIP after the inspiratory check valve. Older style absorbers require the use of a second gauge when a PEEP valve is used for clinical reasons (discussed below). Gages on older designs only display interior absorber pressure. When the inspiratory check valve closes, they do not display true airway pressure and do not reflect PEEP.

In an effort to address some of the limitations of the relatively simplistic time-cycled, volume-controlled ventilators that are typically found in anesthesia, manufacturers are introducing a new generation of absorbers that are more fully integrated into the machine. This design approach has advantages and disadvantages. New designs can be sterilized. While not required in the United States, parts of the European Community require that breathing circuit components be sterilized between patients.

One significant point to consider is that absorbers require daily service and therefore have greater potential for problems such as leaks. Although they are designed with this in mind, personnel who are not technically trained might partially disassemble the absorber. The system is subject to repeated changes of disposable breathing circuit tubing, spills, daily cleaning, and absorbent changes, and is otherwise exposed to a demanding environment.

Absorbent

Various commercially available absorbents are used to absorb carbon dioxide. For practical purposes, the CE and BMET must be aware and concerned with the absorbent’s systematic application and its use. By-products of the chemical reactions between the

absorbent and CO₂ are beneficial to the patient and to the proper function of the absorber. However, one reaction might prove to be a hindrance in excess. Removal of carbon dioxide is clearly beneficial and a primary function of the absorbent. In the process, a chemical reaction produces a color change in the absorbent, which acts as a visual indicator of the absorbent's activity. The color of absorbent changes from off-white to violet as its ability to absorb carbon dioxide diminishes. Under certain, but rare, conditions, the color change reverts to the original. A more common problem is that users overlook, or forget to notice, the color change. In addition, optical properties of the housing can change, thus making the color change difficult to see. Channeling occurs when respiratory gases take the path of least resistance and channel through a relatively narrow cross-section. This can result in unwanted inspired carbon dioxide.

Heat and water are by-products of CO₂ absorption. The heat generated is not excessive and is beneficial to the patient because it helps to warm cool supply gases, which could irritate the lung lining. Water produced is also beneficial because supply gases are dry, and added moisture reduces lung irritation. If water production is neglected, it will build to the point where it could contribute to problems in the breathing circuit. The most frequently noted problems are sticking expiratory check valves from surface tension between valve disc and housing, and water accumulation in hoses and tubing to the ventilator, affecting proper function by inhibiting proper pressure sensing and gas flow.

Gas Scavengers

When the machine is set for an FGF rate of anything higher than the patient's uptake (normally 200–300 ml of oxygen per minute for most adults), any excess must be removed to avoid a build-up of volume as discussed above. Although PEEP is used for certain clinical indications, its uncontrolled application is disastrous for the patient. The scavenging system plays a vital role in conjunction with the breathing circuit to prevent this from happening. During automated ventilation, the bellows pop-off valve opens at the end of tidal expiration to divert excess volume to the scavenging system. During manual ventilation, the user must open and close (as necessary) an adjustable pressure-limiting (APL) valve to set the upper limit for breathing-circuit pressures. If the APL valve is open, or any pressure occurs in excess of its setting, gas flows to the scavenger. The physical construction of scavengers used on the machines varies and can require user interaction. The various designs offer their own risks and benefits; some put greater demands on the hospital infrastructure (vacuum pumps), while others require the user to make adjustments according to FGF rate.

PEEP Valves

During spontaneous ventilation, the body maintains a residual volume in its lungs to prevent them from collapse. During positive-pressure ventilation, the ventilator maintains a slight PEEP (2–3 cm H₂O) to accomplish the same. Clinical indications (e.g., adult respiratory distress syndrome [ARDS]), PEEP valves are used to increase the resistance that a patient encounters during exhalation, increasing the residual volume in their lungs. Different models of PEEP valves can be permanently installed either on the machine/absorber or temporarily on the expiratory limb. For the latter, the design is a variation of a check valve, making it dangerous if installed backwards or in the inspiratory limb, as it would result in little gas flow and inadequate oxygenation (Figure 90-4).

Humidification

As discussed previously, supply gases are dry and can irritate the lung's lining, particularly with susceptible patients who are on the machine for extended periods. Although the use of active humidifiers has declined over the years, they may still be used for certain patients. Two techniques are used to maintain moisture in the gas that the patient breathes: The heated active humidifier and the heat moisture exchanger (HME).

Figure 90-4 Example of a PEEP valve.

Active heated units are generally more effective in adding both humidity and heat to the breathing circuit. The operator must connect the unit to an electrical power source, must monitor its temperature, and must clean and fill them. Many units incorporate check valves to prevent inadvertent delivery of fluid to the patient if they are installed incorrectly. Backward installation can result in significant flow restriction and inadequate oxygenation. These units are installed in the inspiratory limb and have a predetermined "in" and "out."

HMEs are single-use, disposable units. They are connected to the distal end of the breathing-circuit tubing that is proximal to the endotracheal tube. Their primary function is to maintain as much heat and humidity as possible in the patient while preventing heat and humidity from entering the absorber. HMEs are occasionally known as "artificial noses."

Ventilators

Ventilators (Figure 90-5) free the users' hands so they are able to perform other tasks. It is a way to apply cyclical pressure to the equivalent of the breathing circuit bag at a controlled rate and frequency. An expiratory valve inside the ventilator closes during the inspiratory cycle to direct drive gas into the bellows housing, creating a positive pressure forcing breathing circuit gases to flow. At end inspiratory cycle, the expiratory valve opens, releasing drive gas from the bellows housing, and returns the patient to atmospheric pressure. The working gas that is used to drive the bellows varies by country, as discussed previously. Comparable components between manual and automatic ventilation are the bag and bellows and APL and bellows pop-off valve. The bag and bellows offer a means to buffer a volume as gases move in the breathing circuit. The APL and bellows pop-off valves control removal of excess gas from the breathing circuit to the scavenging system, as discussed previously. Both valves require a small amount of PEEP for preferential flow into the bellows (rather than the scavenger) but the bellows pop-off is set a fraction higher, at about 2–3 cm H₂O.

Pressure versus Volume-Controlled

Historically, anesthesia ventilators have been relatively simple, time-cycled, and volume-controlled which might or might not meet the changing health care environment. Patient care can be classified as acute or noncritical. Acute care is a growing population at larger teaching hospitals, as sicker patients are moved out of smaller community hospitals by modern health management organizations. This patient population is challenging to manage and requires equipment that is more sophisticated. Noncritical care machines should be simple to use, with relatively little user-interface complexity.

One example of the limitations of traditionally simplistic anesthesia ventilators is in the function of the bellows pop-off valve. It closes completely during inspiration so that FGF mixes directly with the set tidal volume delivered. Changes in FGF will affect actual volume delivered as a function of inspiratory time; the greater the flow, the larger the tidal volume without making any changes to settings. In response to the growing market of acute care ventilated patients, manufacturers have begun to incorporate more complex pressure-support/controlled ventilators into their anesthesia machines.

Airway Pressure Monitoring

Most volume-controlled ventilators are pressure-limited and will not deliver settings if pressure limit is triggered. Some have an adjustable pressure limit, and others are preset. The transducer, which senses patient breathing-circuit pressures, is physically located in the ventilator fed from a tube taped into the breathing circuit. As mentioned above, this should be in the inspiratory limb after the check valve, but its location can vary depending on machine vintage (Figure 90-5).

Oxygen Concentration

The American Society for Testing and Materials (ASTM) standards require an oxygen concentration measured in the inspiratory limb that turns on with the machine and has a battery backup. Most utilize galvanic fuel-cell technology, which involves a chemical reaction between an electrolyte and two poles (anode and cathode), similar to those of a battery. The reaction produces an electrical potential relative to the oxygen concentration that is measured and displayed. It has a relatively long time constant and cannot provide breath-to-breath oxygen concentration.

Paramagnetic technology is incorporated in some CO₂ and agent monitors. It has a fast enough response to overcome the limitation of galvanic fuel cells but is more expensive. Using a switched magnetic field, it exploits oxygen's natural magnetic properties to create a pressure differential between gas streams (sample and reference), which is detected and displayed as a concentration (Ehrenwerth and Eisenkraft, 1993).

Volume Measurements

Given the limitations of relatively simplistic volume-controlled ventilators, volume measurement is the most accurate device currently in use to provide users with feedback of what tidal and minute volume is actually delivered to the patient. Because of compliance of gas, breathing circuit tubing, and additional dead space in the circuit, the measurement is close, but not exact. A vane anemometer measures a volume of gas by means of monitoring the mechanical rotation of a vane or blade. These devices can be either analog or digital. Technology in newer machines includes ultrasound using Doppler acoustical properties between two points to measure gas flow. Hot wire systems measure energy requirements and changes of a heated wire within a housing as gas volume cools the surface. Pitot tubes in opposing directions working in conjunction with differential pressure transducers are also used to measure flow.

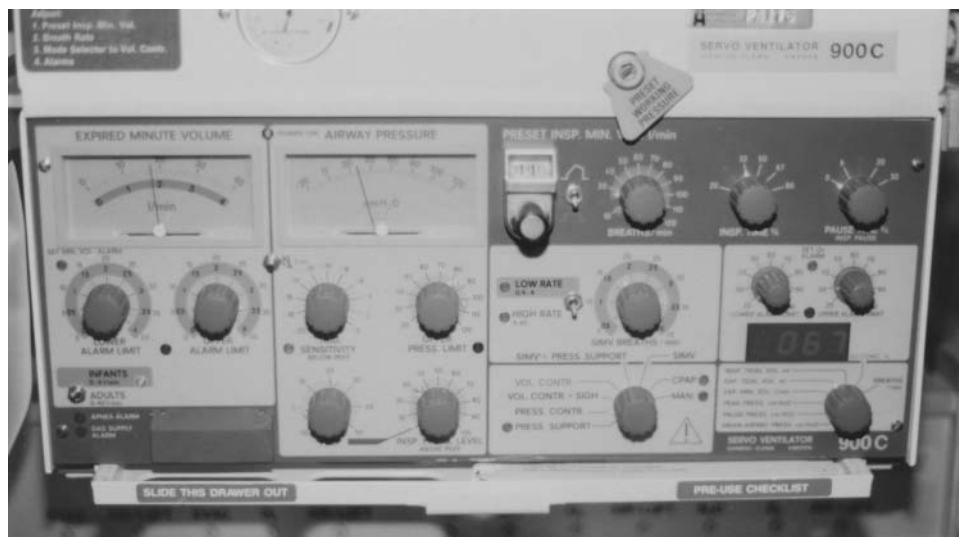

Figure 90-5 Siemens-Elema 900C ventilator.

Associated Alarms

Many of these measurements are, primarily, a means to inform the user of the possibility of a problem, such as disconnect or leak. Oxygen monitors identify potential hypoxic mixtures and catastrophic events and cannot be set below 18% without alarming. Pressure alarms can be used to indicate significant changes in the patient's condition or restriction in the airway. Subatmospheric alarms indicate the possibility of an active vacuum in the airway, or whether the patient is drawing a negative pressure by fighting the ventilator.

Monitoring

The American Society of Anesthesiologists (ASA) (ASA, 1998) has set minimum requirements for monitoring during anesthesia. Depending on the patient's acuity and other factors, such as the surgical procedure and anesthetic plan, the level of monitoring chosen by the anesthesiologist can exceed minimum requirements to include invasive pressures (arterial, pulmonary artery, and central venous), neuromuscular blockade, and consciousness.

The first requirement of the ASA monitoring standard is "qualified anesthesia personnel. . ." The care provider is ultimately the most important monitor and must be able to concentrate on the patient without considerable distraction. Secondly, but no less significantly, the standards specify monitoring for oxygenation, ventilation, circulation, and temperature. Continuous physiological monitoring is used during anesthesia, utilizing plethysmographs, electrocardiograms, and oscillometric devices. Figure 90-6 shows a pulse oximeter used for monitoring the patient arterial blood-oxygen saturation, S_aO_2 .

Studies have shown that although a large percentage of mishaps during anesthesia were due to human error, a significant number were related to equipment failures related to leaks, misconnects, gas-flow-control errors, and circuit disconnects (Cooper et al., 1984). Two of the ventilation monitors (oxygen and volume) were discussed previously. The ASA standard requires that there be a device to detect a breathing-circuit disconnect and that it must have an audible alarm. Along with the use of pulse oximetry, the ASA specifies that there be adequate lighting and exposure to assess patient color and proper oxygenation. This serves as a reminder that one cannot rely solely on monitors. Taking care of a patient is ultimately the responsibility of the provider, not of the monitor.

Capnometry and Agent Analysis

ASA standards originally stated that capnometers would be used to verify the presence of carbon dioxide to ensure tracheal, versus esophageal, intubation. The latest revision spec-

ifies continuous CO_2 measurement. There are clinical indications that can be detected using capnometers. Apnea caused by disconnects, ventilator failure, and complete obstruction in the breathing circuit or the scavenging system can be detected, possibly early enough before arterial blood-oxygen desaturation occurs. CO_2 waveforms during controlled ventilation display characteristics that help the physician to identify potential patient-management issues. An abnormally slow rise can indicate a restricted airway or kinked endotracheal tube, while a baseline drift can indicate a faulty expiratory limb valve, consumed CO_2 absorbent, or channeling. BMETs and CEs should learn typical and atypical capnograms and their causes. This knowledge assists in field troubleshooting and in communication, especially when a physician states that the CO_2 waveform looks peculiar.

Monitors can be divided into two categories: Side stream or mainstream measurement devices. Side stream monitors remove a small sample from the breathing-circuit gases and delivers it to a measurement chamber. The effluent can be either scavenged or returned to the expiratory limb to be recirculated. Mainstream monitors measure the patient's expired carbon dioxide concentration through an optical window in a tube connected to the breathing circuit, most often at the end of the endotracheal tube.

There are a number of different technologies employed in side-stream monitors, including mass spectrometry, infrared (IR) analyzers (single and dual beam), and Raman spectroscopy. The advantages of a side stream monitor are the simplicity of items connecting to the breathing circuit and the ability to read multiple gases. The ancillary items do not need to be reprocessed, are disposable (thus minimizing risk for cross-contamination), do not need optical properties or cleanliness, and therefore are easier to use on a daily basis. The components added to the breathing circuit are physically smaller—an added advantage when working with limited access and sterile drapes. Their largest drawback is in working with expired water. The sampling tube can condense water vapor, and if the monitor is unable to clear the droplets on its own, it requires user interaction. Many monitors incorporate a water trap that must be emptied on occasion, and hydrophobic filters that can occlude.

Molecular asymmetry is required for IR light absorption, resulting in vibration or rotation of dipole bonds. Nonpolar molecules, such as oxygen and nitrogen, do not absorb IR energy and cannot be measured with infrared spectroscopy. Absorption correlates with the number of molecules, so it is an absolute, and not a relative, measurement. Carbon dioxide absorbs IR light at about 4.3 μm , nitrous oxide (N_2O) about 4.5 μm , and volatile anesthetic agents range from 9–12 μm . Because CO_2 and N_2O absorb IR closely to one another, there is signal bleeding between the two. As a result, some CO_2 monitors need N_2O compensation when calibrated. In the monitor, the sampled patient gas runs through water-permeable tubes to dry the moist sample prior to delivery to the measurement bench. Water vapor absorbs IR at the same spectrum and therefore is a contaminant for CO_2 measurements. To measure different gases, dual-beam infrared spectrometers use a spinning wheel with band pass filters to tune its spectrum for the particular gas of interest for maximum signal and a reference. The reference is a zero or minimal response point to which to compare the measurement. Absorption is detected and displayed as a waveform and number.

Volatile anesthetic agents can be measured using infrared spectroscopy and have individual signatures at different wavelengths. Some monitors require simple software updates to read newer agents, while others require more extensive replacement of hardware. Unfortunately, there also are models that are cost-prohibitive to update.

End-user calibration of side-stream monitors involves a zero and span setting. Newer-style monitors have automatic zeroing where room air sample is taken internally. Older monitors require the person completing the calibration to remove the sampling line from the breathing circuit, and then to complete a sequence of actions (i.e., turn knobs or activate keys). Span requires the person calibrating to use a known calibration gas that can be specific to the model of monitor. The calibration gas is sprayed into the sampling port, and the upper measurement range is established either by software or physically setting a potentiometer.

Existing mainstream monitors are more common for use outside of anesthesia due to technology constraints as they are limited to measuring only one gas. They are frequently found as options on physiological monitors.

Figure 90-6 Ohmeda Biox model 3740 pulse oximeter.

Temperature

Temperature is the last physiological parameter mentioned in the ASA monitoring standard. Patients undergoing anesthesia frequently experience hypothermia caused by the mechanics of anesthesia and skin exposure to the cold environment of an operating room. Induction of anesthesia suppresses the body's ability to regulate core temperature at the most fundamental state. An individual who is awake will make behavioral changes (e.g., in terms of dress or shivering) when sensing a change in environmental temperature. The hypothalamus responds to temperature changes and induces vasodilation or restriction as necessary to control and redistribute blood volume regulating core and peripheral body temperatures. Most volatile agents impair vasoconstriction, potentially altering blood-volume distribution. Greater blood volume in extremities increases heat loss, thus lowering core body temperature. Muscle relaxants and anesthesia otherwise clearly inhibit shivering and reduce heat production by resting muscles (Morley-Forster, 1986).

Accidental hyperthermia during anesthesia is not common in the United States, as most all operating rooms are air-conditioned. Hyperthermia is more common in tropical climates, in operating rooms without air conditioning. Malignant hyperthermia can be detected by monitoring the patient's temperature, but an increase in expired carbon dioxide is an earlier indicator.

Thermistors are most commonly used to measure the patient's temperature. Their use poses little risk to the patient; they are reliable and relatively simple to use, and they provide an accurate measurement when used correctly. The most frequent measurement location is nasopharyngeal. The most common problems are cooling from respiratory gases from leaking and misplacement. These devices generally consist of probes that connect to a temperature-sensing device, either a stand-alone box or integrated into a cardiovascular monitor. Thermistors are also used in pulmonary artery catheters, which are used for invasive pressure monitoring and provide a core-temperature measurement.

Infrared tympanic membrane measurement can provide an accurate core temperature but is susceptible to user error. An infrared scanning device with disposable protective cap is inserted in the ear canal, where the energy radiated from the tympanic membrane is measured, converted, and displayed as a temperature.

Liquid crystal thermometers are available to measure skin temperature. However, because skin temperature does not correlate well with core temperature, their use is not practical in anesthesia.

Peripheral Nerve Stimulators

Peripheral nerve stimulators are used to provide an indicator of neuromuscular blockade or otherwise general paralysis. During anesthesia, muscle relaxants are most frequently used to relieve natural muscle tension to facilitate intubation and surgery. In an intensive care unit, muscle relaxants can be used to aid the use of mechanical ventilation. The drugs used are characterized as depolarizing or nondepolarizing. They work by blocking neuromuscular transmission, thereby reducing the muscle's ability to contract, and paralyzing the patient. Paralysis can be achieved also at high doses of volatile anesthetic agents. One important distinction is that a patient can be paralyzed but may not necessarily be anesthetized. Failure to render the patient unconscious results in a most undesirable situation in which the patient can experience excruciating pain of surgery yet, because of paralysis, is unable to cry out or otherwise signal to the surgeon.

Peripheral nerve stimulators (also known as "twitch monitors") are relatively simple pulse generators. Most stimulators are battery-powered devices that connect to the patient by means of a cable and electrodes. Most often, the electrodes are similar to those used for ECG monitoring but can be specific for the application. Most monitors provide information to the physician by pure observation. The user must feel and observe the patient's reaction to the electrical stimuli. There are units available that can monitor the patient's reaction electrically and/or mechanically and can display patient characteristics (electronic or paper chart recorders). These units are used less regularly, often for teaching purposes.

Most frequently, the electrodes are placed over the ulnar nerve near the wrist. The location preference is primarily related to muscle innervation. The ulnar nerve solely innervates the adductor pollicis muscle. Stimulating the ulnar nerve minimizes the possibility of cross talk with other muscles, allowing the user to monitor for a response only on the patient's thumb. Less frequently, the electrodes can be placed on a facial nerve if access to extremities is difficult.

Twitch monitors generate a single-phase DC pulse, normally of a fixed duration and adjustable current. Preprogrammed units are available that deliver pulses in sets to help the physician to identify the state of neuromuscular blockade. The most common pulse sets are:

- Single twitch—upon demand, every ten seconds or one per second
- Train of four—a set of four pulses at half-second intervals or can be set to repeat every twelve seconds
- Double burst—a set of three pulses, 20 milliseconds apart, followed by another similar burst 750 milliseconds later
- Tetanus—Repetitive, single pulses at 50 Hz or greater

Darkroom

Medical imaging predates the recording of an electrocardiogram (ECG) by about eight years. X-rays were discovered on November 8, 1895, by Wilhelm Roentgen. Seven weeks later, Roentgen conducted additional research and published his findings. He did not apply for patent protection on his discovery. He was awarded the Nobel Prize for Physics in 1901. Many of the top scientists of the era became involved with X-rays, including Maria Skłodowska, Pierre Curie, and Thomas Alva Edison. Clarence Daley, who worked with Edison, provided the next important milestone in the development of imaging when he died in 1904 of radiation poisoning. Progress was slow for many years as other applications of X-rays were developed, such as treating acne and tonsillitis and viewing feet in shoes at the local department store to ensure a good fit. After World War II, mobile vans were equipped with X-ray units for screening the population for tuberculosis.

In the late 1940s, sonar, which used to detect underwater objects, was adapted in Japan for use on patients to view internal organs and structures. This technology arrived in the United States during the early 1950s, mostly as a research method, and did not enjoy wide clinical use until the late 1960s. The 1980s brought color to ultrasonic imaging, and in the 1990s three-dimensional images were developed.

In the 1970s, computerized tomography (CT) was introduced, but its wide spread use was hindered by high costs and low reliability. As electronics advanced, so did CT. It is now rare that a hospital does not have at least one CT scanner. In addition, size has decreased to the point where portable CTs are now manufactured. Now, the scanner can be brought to the patient, instead of bringing the patient to the scanner.

The 1980s brought the introduction of a technology known as "nuclear magnetic resonance (NMR)." For obvious marketing reasons, the name quickly changed to magnetic resonance imaging (MRI). The nuclear reactor accidents at Three Mile Island and Chernobyl made anything containing the word "nuclear" a concern to the general population. With patient-movement problems and long scan times in the magnet field reduced or eliminated, MRI is now one of the primary diagnostic tools in health care.

The 1990s brought positron-emission tomography (PET) and single-proton emission computed tomography (SPECT) imaging. These are just starting to become available in more than a few hospitals. As with CT and MRI before that, costs, reliability, and reimbursements have limited the widespread use of PET and SPECT technology.

Now, several imaging technologies are combining to diagnose and treat patients.

X-Ray Generation

X-rays are electromagnetic energy at short wavelengths, generally 0.1 to 1 angstrom. (An angstrom is 10^{-10} meter.) Because the wavelengths are so short, they behave like particles rather than waves, so the names "photon" or "quantum" are used to indicate small quantities of energy. As the frequency of the wave doubles, so does the energy. This means that for the same voltage and current settings, by increasing the frequency (reducing the wavelength) the energy (radiation) doubles.

Photon (quantum) energy is measured in electron volts (eV). An electron volt is the amount of energy that an electron gains when it is accelerated over a voltage difference of 1 volt. Clinically useful X-rays are in the range of 45,000 eV. As electrons from a source (filament) are accelerated and strike the target (anode), heat is generated, and two types of X-rays are produced: General and characteristic radiation.

General radiation, also known as "breaking radiation," or "*bremstrahlung*," is the X-ray that is generated when the accelerated electron passes near the nucleus of an atom in the target where it is deflected and decelerated. When this occurs, a small amount of the total energy (1%) is emitted as X-ray, and 99% is in the form of heat.

When the accelerated electron, passing near the nucleus of an atom in the target, collides with and ejects an electron from one of the inner rings of the atom, characteristic radiation is generated. An electron from one of the outer rings will move to replace the ejected electron, and as it moves, it emits an X-ray.

The "intensity" of the X-ray beam is the number of photons in the beam, multiplied by the energy of each photon (both general and characteristic), measured in units of electron volts or Roentgens per minute (R/min).

The X-Ray Machine**X-Ray Tube and Housing**

CEs and BMETs working in the field should never replace an X-ray tube, as this requires considerable skill and specialized equipment. What CEs and BMETs do replace in the field is the tube housing, which contains a new tube that has been aligned in an oil-filled housing. The first step in understanding X-ray technology is to know what comprises a tube and what some of the problems associated with the tube are.

All tubes contain three basic parts:

1. An enclosure, generally made from borosilicate glass, but some high-power tubes may have metallic or ceramic enclosures.
2. A filament made from a tungsten alloy.
3. An anode, or "target," that is made with tungsten or other metals and backed with copper.

Most tubes will have several filaments, one for each focal track on the anode; a "focusing cup," or cathode, to better direct the electrons moving from the filament to the target; and a target, the anode, that has one or more focal tracks machined in and that rotates at up to 20,000 rpm. The various parts are assembled in the enclosure, which is sealed under vacuum. The material that is used to seal the enclosure must have the same expansion characteristics as the enclosure so that the vacuum is not broken when the tube heats up. If the enclosure is not adequately evacuated, internal arcing can occur resulting in inconsistent output (gassy tube). Sometimes this can be corrected by a process called "seasoning," which is performed when the tube is installed or reactivated after not being used for a long time.

Filament voltages range from 2.5 to 15 volts, and each filament in the tube could have a different voltage. The filament current range is generally between 3 and 6 amperes. Tube current is measured in milliamperes (mA). When the unit is energized and in a keep-warm state, the filaments are constantly on. Because the filaments are kept warm, they release some electrons that are kept confined by the focus cup (cathode). The focus cup also aims the released electrons at the target when the system is generating X-rays.

The anode (target) of a tube is a disc about 10 centimeters (cm) in diameter and 2 cm (or less) in thickness. The disc surface is a tungsten alloy over a copper base. Copper is used for its heat conduction properties. Electrons, accelerated from the filament, hit one or more of the angled surfaces on the disc, called "focal surfaces," or "tracks," to generate X-rays. In all but the simplest tubes, mostly those in dental X-ray units, the anode rotates. The rotating anode allows the heat (recall that only 1% of the energy is in X-ray and 99% is heat), to be distributed over the entire target. This also keeps the focal surfaces from being distorted from the heat, which keeps the focal spot consistent and increases the life of the tube. The bearings on the anode are sealed and self-lubricating and cannot be serviced in the field.

The tube is placed into a tube housing, where connections are made between the filaments and anode and the exterior connection on the housing. In most cases, the housing is then filled with oil, which acts as both an electrical isolator and a thermal conductor to conduct the heat away from the tube. The tube housing is cooled by way of conduction in low-use application, by convection with a fan in higher-use settings, and with cooling systems in the highest-use systems. Tubes are rated in heat units (HU) and will shut down if the rating is exceeded. Tube housings with fans must be cleaned on a regular basis, to ensure good cooling. Fluid levels in the tube housings requiring cooling systems also should be checked on a regular basis. On one side of the tube housing will be a "window" where the X-ray beam exits the tube housing. This can be plastic or glass and might have tape or some protective material over it for shipping. It must be removed before mounting the collimator to the housing. Several recent studies have indicated that the oil loses its ability to conduct heat after prolonged use and may contribute to shortened life of the tube. An indication of the problem is in tube "sputtering" (non-linear output or radiation), below the average HU units at which sputtering occurred in the past. HU problems are rare with X-ray film studies but are common with fluoroscopic studies. One is advised to document carefully the procedures that were being performed when the tube started to "sputter."

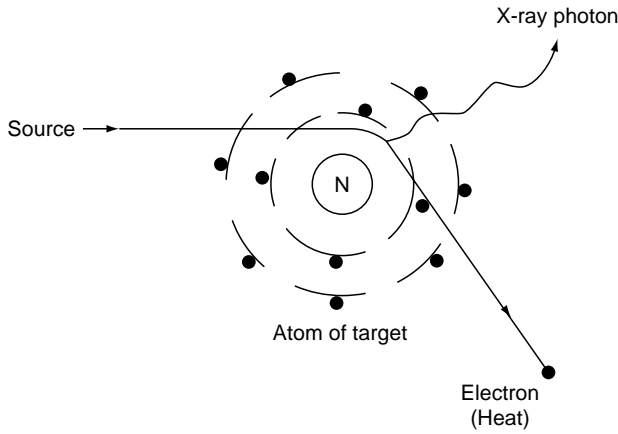

Figure 91-1 Production of general radiation.

Figure 91-3 X-Ray output.

Figure 91-2 Production of characteristic radiation.

The focal spot of a tube is a function of the geometry of the target, target material, texture of the target material, size of the filament and the focus cup (cathode), plus any wobble that might occur in the anode as it rotates. Figure 91-7 illustrates how these factors typically interact. Focal spots are stated in mm, typically 0.3, 0.5, 1.0 and 1.5 mm. Measurement of focal spots is made using a pinhole camera or a star pattern. With a pinhole camera, the image is measured and divided by the amplification factor. The star pattern requires calculations that are more mathematical and it is sometimes difficult to establish where the line blur occurs. These measurements are made at the factory and by a physicist during validation testing. The focal spot size, as built, is listed on the tube housing and serves as a reference point during future validations.

Figure 91-4 Simple tube with stationary anode, low duty cycle.

Figure 91-5 Same tube with focus cup (cathode).

As the tube ages, the focal spot will increase in size. Some of the growth in size can be compensated for by changing "techniques," i.e., voltage, current, and time settings, by the technologists. The smaller the focal spot, the better the resolution of the image. While that is the "official" line of thinking, the consistency of the X-ray generated also affects the resolution. This is evident when edges of objects are not sharp but blended. The use of filters and grids can increase sharpness, also called "clear image" or "central area," and can decrease the blurred/blended area, also called "edge gradient" or "penumbra." The testing of a new tube at installation should include documenting not only the size and shape of the focal spot, but also any tilt, blurred edges, or uneven radiation. A hard copy of this information should be kept on file as long as the tube is in service.

The focal spot geometry produces an uneven beam of X-ray called the "heel effect." This means that there is more energy at one end of the field than at the other. Ideally, aligning the tube so that the radiation caused by the heel effect is directed toward the thickest part of the object being studied helps to maintain the density (i.e., how dark the film is) and contrast (i.e., darkness relative to surroundings) of the film. If complaints about density and contrast arise suddenly, one should check to see that the tube has not been rotated.

Most of the preceding material in this chapter has concerned areas into which BMETs cannot, or should not, venture, or it was simply background information. The remaining

Using Pinhole Technique

Figure 91-7 Focal spot, using a pin hole camera, when alignment is 15° off in any direction.

Less X-ray → More X-ray

Figure 91-8 Star pattern test, look for missing lines.

material addresses items on which BMETs or clinical engineers actually work. Because of this, an attempt is made to use clearer language.

Collimation of the X-ray beam starts with the tube design, specifically the focal spot track, which focuses the majority of the X-rays generated in one direction. The tube housing further reduces stray radiation and continues the collimation process. The beam then exits the tube housing through the "top hat," a lead cone with a rectangular hole in it that sets the maximum film size that can be exposed at a given distance, also called "source-image distance" or "focal-film distance." This also shapes the beam and helps to reduce stray radiation. The collimator mounting block (which is made of aluminum) and the rotation ring secure the collimator to the tube housing. These items should be checked regularly to ensure that the hardware is secure. One old trick is to use a dab of nail polish on the screw head to housing surface. Cracked nail polish will indicate that the hardware is starting to loosen.

On some collimators, there is a slot in the housing, near the mounting block, that allows for the placement of filters in the X-ray beam. These are thin sheets of copper or aluminum (but other material could be used) that are inserted to remove spikes in the radiation intensity that are generated by characteristic radiation, and to smooth the remaining radiation so that it is consistent. This is also referred to as "hardening the beam" or removing soft radiation. These filters should be added or removed only as directed by the physicist doing the radiation certification on the unit. The certification might need to be redone after major repairs to the generator, but otherwise it is done as required by local and federal regulations. The maximum length of certification is three years. Commonly, technologists readjust their techniques after filtration is added or removed. In addition, it is common to experience an increase in "retake" films immediately after changes are made in the system, based on the requirements of the physicist. CEs and BMETs need to work closely with the department supervisors and technologists to ensure that the retake rate returns to, or decreases below, the previous level.

The upper-level shutters are below the filters. These are flat, lead alloy strips of metal that have beveled mating edges to totally block X-ray passage when closed. The upper-level shutters are mechanically linked with the lower-level shutters, so they work together. On some units, there is a feature called "automatic collimation," where the unit senses the size of the film cassette installed and automatically adjusts the shutters to that size. When a problem occurs with the automatic collimation, it is generally traceable to the sensors in the Bucky tray (see below). With manual collimation, problems generally are based in the adjustment knobs or the linkage between the knob and the shutters.

A lamp and a radiolucent mirror are in the space between the upper and lower shutters. This is called the "aiming light," "centering light," "collimation light," or "field light." The light beam is focused through the protective lens on the bottom of the collimator, which has cross hairs to align properly the tube with the area of the patient to be X-rayed. The alignment of the centering light to the film cassette must be checked during each preventive maintenance (PM) inspection to ensure proper alignment. The lamp is replaced from the side of the collimator, never by removing the protective lens with the cross hairs and reaching through the shutters. The light should only remain on for less than a minute.

As part of a PM, the shutters should be fully closed, and a film should be exposed. There should be no exposure on the film if the collimator is working properly. If the shutters do not fully close, the exposure will indicate the shutter that is not closing or that is damaged. A damaged or malfunctioning shutter can adversely affect the quality of patient films and can result in retakes. Retakes are costly and expose the patient to additional ionizing radiation.

At the bottom of the collimator on some units are channel slides that are used to mount cones, cylinders, or other shaped metal units to focus the beam further to an even smaller spot on the patient. These are mechanical devices, and must be checked only when purchased. The security of their mounting does require checking at PMs.

As the X-ray beam passes through a body striking hard or soft tissue, some of the beams are deflected, and some will trigger the release of "characteristic" radiation, all of which can cause the lack of definition of the object being studied. By placing a grid between the patient and the film, deflected and Compton scatter radiation is reduced, thus giving a sharper image on the film. Compton scatter is caused by X-ray beams reacting with body parts and creating secondary X-rays, similar to chromatic radiation. Two basic grids are used: A parallel grid, and a focused grid. Focused grids are limited in that they are designed for a single source image distance (SID) or focal film distance (FFD).

Grids come in various ratios of the height of the strip to the space between strips. One common grid is 8:1, where the lead strip is 8 times as high as the space between it and the next strip. The common ratios in use are 5:1 for low-voltage work, 8:1 for mid-range voltages, 12:1 general purpose (the most common), and 16:1 for high-voltage work. The next item to consider is the spacing of the strips. The common choices are 30 strips per centimeter for general use, 45 strips for skull studies, and 60 strips for vascular studies. In most cases, the technologists can change grids as needed, without clinical engineering involvement. When the technologist has a problem with a grid, it generally involves poor films. Two common problems are the cases where the grid is not installed flat or is installed upside down, especially with a focused grid. Occasionally, they will be off-center, thus resulting in film edges that are not clear, and contrast that is off on one or more edge.

If the films come out with noticeable grid lines, there is a problem with the "Bucky." Dr. Hollis Potter and Dr. Gustav Bucky, working independently, developed this system in the 1920s. The grid is moved 2–3 cm in one or more directions so that the grid lines do not appear. The movement of the grid is the "clunk" that you hear during an X-ray exposure. The drive mechanism to move the grids can be springs, a motor, solenoids, or some other simple drive. The film cassette is placed in the Bucky tray, which sets the collimator to that particular film size. The grid is mounted over the tray and moves during the exposure. It generally takes more time just to get to the grid to fix the Bucky mechanism than it does to fix it.

The OFD (Object-Film-Distance) is the amplification factor of the imaging system. The greater the distance, the larger the object appears on the film. This is rarely used, but sometimes it is useful in locating breaks in small bones.

Film and Film Cassettes

For most X-ray examinations, dual-emulsion films are used, which means that both sides of the film take the image. These films are more durable than the single-emulsion films that are used for mammography studies (see below). Double-emulsion films tend to be brighter, but they give up some detail.

In the film cassette, two intensifying screens emit light when exposed to the X-ray. This light, along with the X-rays, exposes the film, creating an image. This allows for the patient to absorb a lower dosage, but there is a small loss in clarity of the image on the film. Sometimes the screens become damaged, and the resulting images are not of a high-quality. Sometimes problems with the film-cassette screens are reported as problems with the X-ray unit. One indication of a screen problem is that only one of a group of films has a problem. Finding the bad cassette can be time-consuming. Users also should monitor cassettes for light leaks. This is usually evident by the clear edges of the developed film. When troubleshooting X-ray problems, one always should inspect the last films taken before doing anything with the equipment. The films will provide an unbiased report of what, if anything is wrong with the generator.

Power Supply

Because the maximum voltage of the electrical power entering a hospital from the power grid is 13,800 volts (well below the voltage that is needed to create an X-ray) transformers are used to obtain the needed higher voltages. The highest voltage on hospital floors is 480 volts in a "Y" configuration of four wires.

Simple X-ray units, such as a dental unit, can work on single-phase line voltage, 117 VAC, with a step-up transformer, and with the tube acting as a rectifier. This is a single-pulse system and, as such, it is inefficient; and the quality of the X-ray is not great. This is a half-wave rectifier system where the X-ray is produced only for the short time when the half-wave reaches the critical voltage, (45,000 volts). These are reasonably small and inexpensive units, with a fixed anode, and they rarely require service. One thing to remember is that these units are not well collimated, and stray radiation is common. Patient and user exposure levels are higher than in most radiographic rooms.

In some very old units, the power supply is a single-phase line with full-wave rectification. The rectifiers are in the same "tank" as the transformer. Either vacuum tubes or solid-state components and capacitors smooth the ripple of the full-wave rectification. Most of these units have been replaced in modern health care facilities, but they still can be found in use in a physician's office. Repair parts are hard to find, and some tanks might contain polychlorinated biphenol (PCB) based oil, even though all PCBs were supposed to be replaced in the early 1980s. These were known as "two pulse" wave systems and were found mostly in dental offices.

The majority of medium and high power units installed up to the early 1990s used 480-volt, three-phase power supplies. These were also called "12-pulse systems." When the three legs of the output side of the transformer are combined into DC, the ripple is so small that 95% of the voltage will produce the X-ray, as compared to less than 50% in a single-pulse system.

For voltages of 150,000, as used in angiography suites, step-up transformers are needed. Because of line fluctuation and inefficiencies in transformer designs, a turns ratio of about 1:350 would have to be used. The size and weight of these transformers might require special floor braces and additional room. There could be several in the same area if more than one tube is used. As these units can become hot, especially if constant use is required, heat generation is a consideration. The transformers require regular inspection to check the oil level. Darkened oil in the transformer tank is an indicator of arcing or excess heat. The units also must be examined for leaks, dents, or bulges in the sidewall. All can indicate impending failure of the system.

Most modern X-ray systems use what are called "high-frequency" power supplies. The incoming frequency is amplified to approximately 100 kHz, which allows smaller transformers to obtain the required voltage gain. At these high frequencies, there is no need to rectify the waveform. The X-ray intensity generated is quite constant, which allows the patient to be exposed to lower doses. Most high-frequency power supplies are smaller, lighter, and less prone to failures and can be put in the console, thus freeing up floor space.

One should have service manuals before starting any repairs on the high-voltage systems. "Lockout-tagout" procedures must be used at the location for safety of the person and staff. More than one incident has occurred in which a unit was not properly locked out and tagged out, only to be inadvertently turned on. Not only is there an electrical-shock hazard, but serious damage can be done to the device. It is generally a good idea to have a second person in the area when working on high-voltage systems, for the protection of all.

It is also important that one communicate what one is doing, when one expects to be done, and whether the physicist must be called to validate the system after the repair is completed. This physicist should be notified when any changes are made in the high-voltage power supplies or timing circuits, and when a tube, image intensifier, or video chain (see below) is modified.

Fluoroscope

The original screen fluoroscope was invented in 1895, by Thomas Edison, who promptly patented it. The basic design remained constant for close to 60 years before being replaced by video systems. Fluoroscopic (fluoro) exams view dynamic events in the body,

Figure 91-11 Collimator.

Figure 91-12 Parallel grid.

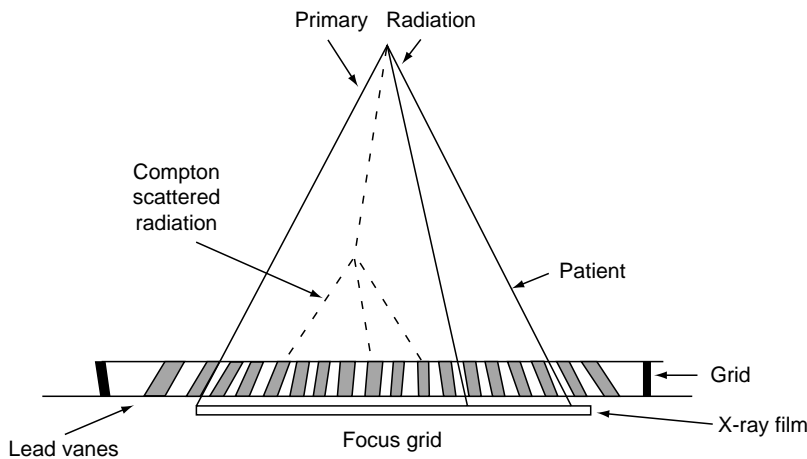

Figure 91-13 Focused grid.

Figure 91-14 Cassette/film cross-sectional view.

such as movement in the intestinal track, or blood flow. It is real-time imaging. If a record is needed, a "spot film" is taken. Some units can be equipped with a rapid film changer, also called a "puck." This unit allows for the quick sequencing of film during a procedure. Some units can have a "multiformat" camera attached to them, in which case up to 32 images can be placed on one sheet of film. The same information that would be recorded by the puck on many sheets of film is done electronically from the fluoroscopic image received by the video system and is transmitted to the multiformat camera. Because the image is captured by a video camera, it can be digitized and manipulated. This is sometimes called "digital subtraction" or "digital subtraction imaging." The fluoroscope works at a lower power level than that required for the typical X-ray film. Therefore, if a film is required, the system goes into "boost" mode to expose the film, and then automatically drops back to its previous exposure level. Generally, patients receive a higher dose of radiation during a fluoroscopic study than they would if only films were taken. Although the

power is lower, the exposure time is longer, thus giving the higher dosages of radiation. Hanging from the sides of the I/I are strips of lead shielding, which must be inspected on a regular basis for secure mounting and adequate coverage.

With the exception of C-arm units (see below), the X-ray tube is located under the table on which the patient is positioned. The tube is in the same type of housing as previously described. However, it does not rotate. The collimator is simpler as it has no targeting light or cross hairs. After the X-ray beam passes through the patient, it is detected by the image intensifier (I/I). At the back end of the I/I is a video camera that amplifies the light generated by the X-rays striking the I/I and displays the light patterns on a CRT. That is the simple explanation of a fluoroscope.

The I/I comes in various sizes, from 3 to 15 inches in diameter; 12- and 15-inch units are not common in newer units as the radiation dose for these is high, and modern techniques allow the radiologist to better target the areas being examined. Some units are

Figure 91-15 Single-pulse wave.

Figure 91-16 12-pulse waveform.

multisized in that either electronically or mechanically they can be set for 6- or 9-inch diameter receiving areas. The I/I is a vacuum chamber, usually made of glass, with a phosphorous coating on the inside of the large end. As X-rays excite the phosphors to emit light, that light is focused at the small end of the tube. The light beam can be linked directly to a camera, split with mirrors to two cameras, or split between a camera and direct viewing ports, which is not common in modern designs. The most common configuration is the direct link to a camera, followed by a beam splitter that links the video camera and a cinematography (*cine*) camera to the light beam coming from the I/I, as in a catheterization installation.

The camera can be a Vidicon, Plumbicon, CCD, or other construction, and is matched to the rest of the video chain. Cameras come in a wide variety of sizes and mounting styles, so one must be careful to specify the correct camera when selecting replacements. On some systems, there may be a photo detector between the I/I and camera that is used to provide the feedback for automatic brightness controls, sometimes called "automatic gain control." In other systems, the feedback is generated after the camera.

Monitors come in a many sizes, formats, and resolutions. On older units, 450–700 lines are used, with the most common being the 525-line monitor. Some newer units use 1024-line monitors. Many units use 1024 × 768 interlaced or 1280 × 1024 or 1600 × 1280 non-

interlaced monitors. The system must be matched from camera to monitor for best results. One should not spend the extra money for a high-resolution monitor if the camera is not capable of the higher resolution. When replacing a monitor, one also must consider its weight if it is "hung" on a floating arm. One might have to rebalance the arm to ensure that it remains stationary when repositioned and that does not float upward or downward.

As previously mentioned, spot film systems, rapid film changers and multi-format cameras are often used for "still" recordings of body structures. For motion studies, videotape and cine film have been replaced with dynamic memory—a computer with a large memory that can document several studies before they must be transferred to a CD, DVD, or optical disc. It is, essentially, a picture archiving and communications system (PACS) unit. Videotape is inexpensive and requires no film processing, but it does not have the capability of high-resolution of small objects that film does. Videotapes are often used as backups for cine and are becoming more widely accepted by the medical profession. These tape systems are not off the shelf, from the local video-supply store, but are professional grade units with "frame grabber," super slow motion, and other features. Cine requires a special developing unit and an editing console to view the films. These are high failure and high maintenance devices that require good PM procedures to reduce costs and down time.

Most fluoro systems have automatic gain or brightness controls. These allow for the automatic adjustment of voltage (KV) and current (mA) during the study so that the contrast and density of the image remain constant. This system can be a source of problems that are often more user-centered than technology-centered. Hard failures are uncommon with these circuits, but often they need adjustments as the tube ages. When a tube is replaced, it is a good practice to reset the gain control to the new baseline of tube output. On some units, this is done automatically.

The Table

The simplest X-ray table is a horizontal surface with limited motion. The film cassette tray—the Bucky—is stationary, as is the overhead tube, and the patient is positioned using the "floating top." The head-foot movement is generally two feet or less, with side-to-side motion of about half the head-foot motion. Once the table and patient have been properly aligned, the top is locked in place using electrically powered brakes. The tabletop is made of a composite material that allows X-rays to pass through it with little or no loss, and no additional scatter. Many of these tops have weight limits of 175–200 kilograms. Damaged tops should be replaced when found, as they could compromise patient safety by contributing to lock failures, poor film quality, infection, and patient injury.

Powered tables have the head/foot and side/side motions along with multicassette trays, plus the ability to move the patient from a prone (i.e., horizontal) position to perpendicular positions. The I/I moves with the angular position so that it is always aligned with the tube under the table. Because there are motor drives that are used to move the table and patient to selected angles, it is common for linens to catch in the drive mechanisms. These should always be covered. When they are not covered, they can present a major potential for a patient injury. In addition, it can put an unreasonably heavy demand on the motors and can lead to failures. The locking systems in tilting tables are critical and should be a major point on any PM program. As with the simple table, the tabletop is subject to damage from heavy patients and should be inspected closely after a heavy patient has been on the table. When performing annual PM inspections on the table, the gearing should be checked for missing teeth and lint accumulation. These two hazards can contribute to premature failures of the drive motors. When working on tables that are used for reflux or voiding studies, one should follow universal precautions procedures for personal protection.

Figure 91-18 Image intensifier.

Figure 91-19 Video chain.

The Overhead Tube

When an overhead tube is present, it is mounted on a track system, similar to an operating room (OR) light, except that the amount of movement is much greater. The overhead tube assembly will move in four horizontal directions. Detents (locking positions) and stops on the tracks are required, to ensure safety and proper alignments. The security of the detents and the stops must be verified on a regular basis. Keeping other devices from infringing upon the area of movement of the overhead tube is difficult. Many devices have been damaged by being hit during the movement of the tube. The end stops on the tracks need to be inspected on a regular basis, to ensure that the tube assembly cannot fall off the tracks. In many installations, a counter-balance system using cables and weights is used to allow easy and smooth movement of the tube. These cables fray over years of use and occasionally need to be replaced, especially with systems that brake or lock by clamping on the cable. Frayed cables on the up-and-down movement of the tube over the patient can be particularly dangerous.

With any locking system, locks will stick open, making it impossible to lock the tube in position. Troubleshooting lock problems is a two-person function. While one person observes the locks, often while standing on a ladder, the other energizes the lock from the tube head handle. Broken wires in the locking system are common. A 10-foot length of wire with alligator clips on each end can be used to locate a broken wire. One end is clipped to the switch, and the other to the lock. If the lock energizes when the switch is activated broken wire is indicated. Replacing lock wires is not easy, as it can be difficult to route the wire properly. Temporary repairs to get through the case or, at worst case, the day should not be considered permanent repairs. Rubber-jacketed wire *should not* be used in any area where radiation exposure is expected. Radiation drives the rubber molecules into the metal, creating high resistances over years of exposure. Use only plastic or Teflon-insulated wires.

The Console

The control unit, or console, is located in a room adjacent to the main room. A leaded glass window protects the technologist from scattered radiation and affords the technologist a full view of the patient (Strzelczyk, 2004). On the console, the technologist selects the technique; i.e., the KV, mA, and time for the exposure. Depending upon the age of the unit, selections are made via rotary switches, push-button switches, paddle switches, or up-and-down rocker switches. On some very old units, the exposure time is set with a mechanical timer (such as an egg timer). While older units might have only an analog meter displaying KV and mA, modern digital units have displays of KV, mA, time location buttons (for skull, thorax, abdomen, pelvis, or extremities) that automatically set the KV, mA, and time for the technologist. Override controls enable the technologists use other settings as needed.

Most problems associated with the console are the same as with any control surface on any device and include loose knobs, stuck switches, and cuts in the membranes that protect panel switches.

The panels may display elapsed-time and dose information when in the fluoro mode, heat units, and other information. Many of the newer units have an alarm-memory system that logs faults in the system. This always should be viewed when any problem is reported. Generally, alarm memories are available only when a special sequence is entered, when the unit is in the service mode. "Technique" errors indicate that the technologist is overriding the automatically selected settings and that he might not be getting proper exposures. This situation could be difficult to handle because, if the technologist is challenged, he could become more critical of the equipment.

The junction box where the wiring from the console connects to the rest of the room can be a problem point. Coffee spills, paper clips, and heavy dust accumulation can short connections out.

When radiologists are performing a fluoroscopic study, they are in the room with the patient and will use either a hand or foot control to control the unit, make spot films, and perform other adjustments. Both are failure points and need constant work. Foot controls are subject to spills, kicks, and general abuse, while hand controls are often dropped, thus causing severe mechanical shock from sudden stop or rapid deceleration. One solution is to put a rubber protector on the hand control, as one would on a pulse oximeter.

On some systems, there are up to five instrument cabinets, two high voltage tanks, and various other components, all of which are interconnected. It is important to inspect all exposed wiring (at least annually) and to keep the cabinets well ventilated and dust free. The manuals should be kept in the area and secured. Some organizations keep service records in a binder in the area, along with any field notices or updates. In radiology service, information is power, and one must protect that source of one's power. It is uncommon for X-ray systems to be connected to the hospital's emergency power system. Most systems can be manually connected to emergency power for short periods if there is enough generator capacity. Commonly, parts of the system are connected to power conditioners or even an uninterruptible power supply (UPS). It is a good idea to list of how each device in the room is powered, as some fluoroscopic video monitors could be on the same power system as the table or control panel and will only work if those systems are energized.

People have gone the extra mile to make X-ray systems more complicated and expensive than they have with any other medical device. One has two to three names for the same functions; one has interconnections for devices two feet apart that will travel 20 feet into the floor or ceiling to a junction cabinet and then back. In addition, costs are high, and alternate vendors for many items are not available. In imaging service, it is almost better to be a good manager of technology than to be a good repairer of technology.

Processors, Multiloaders, and Dry Imaging

In radiographic systems, film is used to document images, not PACS or Dynamic memories. The most common films are blue or green based. Films can have varying speeds, (i.e., varying light needed to expose them), emulsions, (molecules that accept light), base material, single- or dual-sided emulsions, and sizes. There is daylight film, for which no darkroom is required, and normal film, for which a darkroom is required. Combined with daylight or darkroom cassettes that have intensifying screens in them that match the film being used, the chance of mistakes and mismatches is quite high. The film type (blue or green), the speed, the intensifying screens in the cassettes, and the chemicals in the processor all must be compatible, in order to achieve high-quality results. Combining these factors with technique variations (KV, mA and time settings), it is easy to understand why the waste-film bins are always full.

Darkroom Films

Working in a darkroom under a "safe light," the technologist hand loads sheets of film into cassettes by opening the back of the cassette. The cassette is either hand-carried out of the darkroom or placed into a "pass box" where another technologist picks up the cassette and performs an exam by placing the cassette into a Bucky tray and exposing the film with a patient between the source (X-ray tube) and the film. The technologist brings the cassette back to the darkroom or pass box, where the cassette is opened and the film is manually fed into the film processor.

Some of the problems commonly encountered include:

- Light leaks around the edges of the film, indicating that the cassette did not close properly, or that it is defective (look for indications that the cassette has been dropped and damaged)
- Marks on the film caused by dust or dirt on the intensifying screens
- Cover latches not closing properly

Daylight Films

Under normal lighting conditions, packs of films in various sizes are placed into a multiloader by a technologist, usually 100 sheets at a time. The technologist pushes the cassette into the "loading slot," where mechanical fingers open the end of the cassette while at the same time determining its size. The machine selects the correct size of film and uses push rollers to force the film into the cassette. The technologist then uses the cassette for a procedure. After the procedure, the technologist places the cassette into the "unloader," which is attached to the film processor. Mechanical fingers open the cassette and eject the film onto a roller system that transports the film into the processor.

Common problems include the following:

- Light leaks, generally only of one edge of the film, which could be caused by a bad cassette or light exposure to the film as it was loaded into the multiloader.
- Marks on the film caused by the loading or unloading rollers.
- More than one film loaded into the cassette. This is a common problem if the humidity in the multiloader is allowed to get too high.

Film Processor

Auto film processors have changed little since their introduction in the 1960s. The exposed film moves downward into the developer solution, and then back up to the crossover rack that sends the film downward into the fixer bath, and then back up to another crossover rack and down through the rinse bath, and then into the drying rack before being dropped into the developed-film bin on the front of the processor. With each film that passes through the processor, additional chemicals are added to keep the system in balance. If the processor sits for long periods without films being processed, the chemical balance can be affected. Most processors have a "stand-by" cycle, during which developer and fixer are added to the processor every hour, replacing the evaporated chemicals. This can cause problems with the quality control on films, as the concentrations can get too high and thus cause very dark films. It is wise to discourage placing film processors in low-use areas, as they require more care than those in high-use areas.

The solutions used must be compatible with the film emulsions and must be monitored for quality by performing "densitometry" tests at least every other day (or, better yet, every day). A film is exposed with a sensitometer and run through the processor. On the edge of the film is a 21-step exposure that ranges in density from 0.05–3.05 in steps of 0.15. Using a densitometer, three points on the exposed film are measured.

The first point is the film outside of where the gray scale appears from the sensitometer. This is the base, or fog reading, that should remain constant. Next, two steps on the gray scale are measured, such as 9 and 13; this can vary from hospital to hospital and even within a single hospital. The selected steps are part of the quality assurance (QA) program for the radiology department. The measurements from these points are plotted, and any variations longer than two days generally will require either the cleaning of the processor or adjusting the chemical mix or temperature. If all 21 steps are measured and plotted, one would have a characteristic curve of density and exposure. This is also called "H & D curve" (developed by Hunter and Driffield). The QA chart for each processor shows the four key points, the base fog of the film, the readings at each selected step, and the temperature of the developer.

The crossover rollers, or rack, should be cleaned each morning to remove any build up of dried chemicals. Rinsing under running warm water for a minute or less is sufficient to remove any accumulation. If not cleaned, the dried chemicals can lead to "pick off" on the film and could indicate the presence of an anatomical change in the patient that is not there. This can be a serious problem, especially in mammography (mammo) studies.

Most hospitals will have a silver recovery system connected to the processors to capture the silver that washes the films as they are developed. These can cause problems if not changed on a regular basis, and they can impede the flow of water from the processor to the drain. Clogged drains, leaking tanks, temperature changes, and stuck pumps are common problems with processors. If the processor rollers and racks are cleaned on a regular basis, and the rollers are replaced as needed, they are not major problem areas. However, they become problem areas if they are not cleaned. A good QA program must be followed, to minimize problems with processors and to ensure consistent results.

In most hospitals, there is a dedicated film processor for mammo films. These films are single-emulsion films and require temperatures that are different from those of regular radiographic study films.

When digital systems are in place for either fluoroscopic or radiographic studies, the signals are transmitted to a device called a "laser camera" or "laser imager." In this device, the images are scanned onto film and transported into the film processor. These systems are prone to failures and require regular servicing, as with any digital system. One must be aware of light leaks between the laser camera and the processor because they can affect the quality of the film.

A verification of this is called the "dry imaging system" or "dry laser camera." This device takes the digital images and "prints" them onto the acetate-based "film." This is not a true film; it is clear acetate that contains printed images. There is no film processor, no cassettes, no film and no chemicals to mix. It is less expensive to operate, and environmentally friendly, but capable of being used only with digital imaging systems. Some radiologists are not comfortable with it. These units are found mostly in the CT and MRI areas. These systems will become more common as PACS are installed in hospitals. PAC systems are expensive and require major changes in department policies and procedures, but pricing is coming down. As more digital systems are installed in procedure rooms, the better the return will be on investments in PAC systems (Cohen, 2003).

Specialty Units

Specialty units might be physically located not within the main radiology department, but in other areas of the hospital. Mammography and bone-density services are often located in the women's health clinics or in outpatient clinic areas. Tomography units could be located in the orthopedics clinics, while the interventional radiology areas could be close to the operating rooms. The remote locations of these services can strain one's servicing capability. For example, when devices to be serviced are not in the main radiographic area, there are no convenient alternate methods of conducting the specialized examinations. These examinations are generally expensive procedures, and the hospital does not want to forgo reimbursement for them. Rescheduling patients can be a problem, so good PM programs are needed, to keep the "up time" high on these devices and systems and to prevent negative affects on the hospital's financial picture.

Mammography

A mammogram is part of regular testing for women over age 40. This is a soft-tissue radiograph, requiring specialized X-ray equipment and accessories. Originally, when a mammo was done, the collimator was removed from the tube, and a cone was mounted in its place. The cone was lowered to the body surface, and an X-ray was taken. The voltage used was between 40–50 kV, with a long exposure period. It was an uncomfortable procedure, and the dose could be as high as 10 rads. Now, specially designed mammography units, while still uncomfortable for the patient, deliver much lower doses. The use of high-frequency generators has further reduced exposures and has increased contrasts on the films because the X-ray beam is more consistent.

In a mammo procedure, the breast is compressed between adjustable "paddles" that move tissue to a more consistent thickness, and the film is taken. This is a single-emulsion film designed for low-contrast images. The film is developed in a dedicated processor for that type of film. Digital imaging is slowly becoming more common, but its progress has been slowed by reimbursement problems, as many insurance carriers have not approved the use of digital systems in mammography studies. The FDA was also slow in issuing its approval of the technology.

Common problems in mammography units include compression paddles that crack or slip, and mechanical positioning. Replacing the tube is common after two to four years of use and can be expensive. The physicist should closely monitor the focal spot size on the tube to ensure that it does not exceed its specified size range. The growth of the focal spot will affect the quality of the exams. One should obtain from state authorities a copy of the regulations for mammography services and should ensure that the installations meet these requirements.

Some radiologist will also have a dedicated viewing panel for the mammo films. The lights might be brighter and might have more output in the blue spectrum of the light. If this is the case, it is a good idea to replace all of the light tubes at the same time when performing PM.

Tomography

This procedure is known by many names (e.g., "tomo," "tomography," "body-section radiography," "laminography," and "planigraphy.") The basic principle is to blur unwanted images while maintaining the contrast and density of the desired object. The main use of this technique is for examinations of the spine. The operating principle is simple in that the patient remains motionless while the tube and film move in opposite directions. Mechanical problems are the most common, and spare parts are often difficult to obtain.

Another version uses the long cassette and film of up to 30 inches in length. The film and patient remain stationary while the tube moves. Other than the movement of the tube and film, everything else on this unit is standard, including the development of the film.

Bone Density

The loss of minerals in bones had been difficult to diagnose for many years. While tomo exams were used to confirm degenerating vertebrae, they were not practical for mass screening. In the late 1980s, new devices emerged that were specifically designed to measure the density of bones. These systems are simple and generally reliable.

Under the table is an X-ray tube with dual energy ranges (70 and 140 KV are typical). By using a high-frequency power supply, the quality and quantity of the X-rays generated is consistent. Instead of a collimator, which limits the output to a square or rectangular shape, a long and narrow "fan beam" is created. These are rotating anode tubes, and some require additional cooling to maintain the ideal operating temperatures of the tube. The beam passes through the patient and is detected by a series of sensors mounted over the patient. The sensors are connected to a computer, which reconstructs the data into a picture. In most cases, the image is printed out on a standard computer printer (laser or inkjet), with computed densities printed next to the image. If a dry imager is available, the image can be printed on that as well.

Scan times can range from a few seconds, to image a small area, to up to 20 minutes, for a full body scan. The dose levels to the patient are about equal to a chest X-ray, even with the long scan time. Because the beam is so confined, the walls do not require lead lining, and the operator needs no shielding.

On most systems, the patient is placed on the table and positioned at the point where the scan is to start. The tabletop moves the patient past the X-ray tube and detectors until the scan is complete. Because the total movement of the table is about 30 inches, the ends of the table should be kept clear of other devices that could obstruct table movement.

Another version of bone densitometry is the heel ultrasonic unit. This is a small unit that is good for mass screenings but not for definitive diagnosis of patients. The patient places a foot onto the positioning platform of the device, and the heel bone is scanned. If the reflected power is below a certain number, the patient is advised to get a scan using the X-ray system.

Interventional Radiology or Special Procedures Rooms

Interventional radiology (or special procedures) rooms encompass a wide range of rooms, including cardiac catheterization laboratories, angiography suites, electrophysiology suites, and neurology suites. All special procedures rooms are equipped with fluoroscopic capabilities but with better video resolutions, smaller focal spots, higher power, and a multitude of support equipment. Many of these units are almost like a separate practice within the hospital. As the equipment is used for twelve or more hours every day, incorporating it into a PM program is difficult. One must be flexible by servicing these areas at times when, for example, staff are having patient conferences or are on breaks.

The support equipment in these areas includes such devices as defibrillators, multi-channel monitors, lasers, pacer programmers, electrosurgical devices, and radioactive sources used in angioplasty. One might have problems in maintaining a good inventory of equipment in this area as some of the devices may be on loan or consignment, or simply "borrowed" from other parts of the hospital. Care should be taken to follow universal precautions when working in these areas.

Cystoscopy Room

The cystoscopy (cysto) room is generally located in the OR suite and is specially designed to perform studies or procedures relating to the kidney, urethra, bladder, and prostate. It is a fluoro room with a special table. Films are not taken often, as the surgeon uses the fluoro imaging to guide instruments to remove or crush stones. In other procedures, dye is infused into the kidney, and the movement down the urinary track is observed. Another common procedure in the cysto room is the transurethral resection (TUR) surgery of the prostate.

This room is a wet environment, and close inspection of grounding and measurement of electrical leakage currents is essential for the protection of the patient and staff. Generally, this room is available for inspections and PMs in the mid to late afternoons on most days of the week. One should follow universal precautions when working in this area. Probably more than in any other X-ray installation, the lubrication of mechanical systems must be done on a regular basis. In addition, one should check for rusting on the machines.

Portable C-Arm

Portable C-arms are similar to portable X-ray units except that they are fluoro systems. They use a high-frequency power supply and have an image intensifier and view chain to display images. Most have a storage scope where the first image of that patient is kept to serve as a reference and guide to the impending procedure. The systems come in two basic sizes. The larger size units are used in operating rooms, often on orthopedic cases (such as hip replacements) and provide the surgeon with an accurate indication on joint is aligned and seating. They are also used in other cases in the operating room for placement of drains, catheters, and other devices into the patient. Generally, C-arms have two components: The "C," which contains the tube; and an I/I attached by way of cables to the chassis, which contains the generator and the video-storage electronics.

The smaller units, often called "mini C-arms" are commonly used to assist physicians in resetting broken bones in hands, wrists, and feet. Because the mini C-arm is in one chassis, it is easy to move and takes up less space than the larger units do.

Common problems associated with C-arms include the following:

- Interconnection cables are easily damaged, as are the connectors.
- Positioning locks not holding during procedures allow the head to move.
- Casters and caster locks.
- Mechanical damage from running into walls and other objects.

Although technical discussion of CT, MRI, nuclear medicine imaging, PET, SPET, and ultrasound is not included in this chapter, the technical management problems are similar to those associated with the devices described above. Technical management is discussed in the following section.

Management of Imaging Devices

Several hard and fast rules apply to managing imaging devices. These rules do not vary between hospitals and cannot be appealed to the courts.

No matter how capable one is, in the hospital one will not be able to repair every item, every time, in a timely fashion. One needs access to outside experts, whether they are others in one's service company, an independent service organization (ISO), or the manufacturer of the device. Even the field service organizations of a supplier often have to call the factory for guidance on problems. No one knows everything.

One will be overcharged for repairs parts, time, or travel, on a regular basis. Therefore, one should review all service reports and invoices.

One will not be able to locate a second source of all repair parts, especially tubes on newer units.

There often will be a discrepancy between the real problem and what the physicist reports. Performing good PMs that find and correct minor problems before they become major problems brings the greatest financial savings.

It is important that the chief technologist be kept informed of all repair and PM work done in the department. While one need not to give detailed reports, it is a good idea to meet on a regular basis to review problems that have occurred. Some problems could be caused by technicians using poor techniques or attempting tests utilizing a unit that is not suited for those tests.

It is also a good idea to work with the department on any quality issues that effect patient care or costs, especially retakes. When a study or exam must be repeated, extra costs are incurred. More importantly, repeated exams expose the patient to more radiation and, if the test is invasive, to an increased chance of infection. Retake rates can indicate equipment and personnel problems. While these problems are sometimes difficult to separate and to correct, their solution brings with it decreased costs and increased patient safety.

One must be aware of any changes in film, processor, or contrast-media supplies as they may affect the quality of examinations by requiring changes in equipment settings.

One must keep good records of what is done. This is not easy to do, as some of the work will be done "off hours" and the service reports might not be sent to the clinical engineering department. All service reports should be reviewed for completeness and should include, at a minimum, a description of the work performed and the time expended. Reports should be checked also for the "boomerang effect," which occurs in all service organizations. It is not uncommon to have a service call on a device the day after a PM was done, nor is it uncommon to have the same failure within days of a so-called repair.

One should take care in record keeping, which can save the hospital major expenses, particularly on repairs or PMs that were not done or that were done improperly, for which the hospital was billed.

Lastly, when working on imaging equipment, one should "think simple" and should look for the obvious. As with other medical device technologies, adhering to this philosophy usually results in problem solution. One should ask questions and should take the time required to understand the problem fully, before starting any repair.

Melissa Burns

Holyoke, MA

The human observer relies on a wide range of cues, drawing from color, perspective, shadows, and a vast library of particular individual experiences. Visual perception relies on a uniquely human capacity to make judgments. However, a machine-vision system does not have an experience base from which to make comparative decisions. Everything must be specifically defined. Simple problems, like locating an object, differentiating top from bottom, and distinguishing a light artifact from a part of the interesting object, become complicated tasks in machine vision. That is why, in order to reduce the number of variables, the vision system must be provided (from the beginning) with the “best image” possible, meaning the image that makes it easiest for the machine vision computer system to do its task.

“Machine vision” can be defined as “the acquisition and processing of images to identify or measure the characteristics of objects.” The objective of this chapter is to provide useful information on the three steps that are required for successful machine-vision applications: Conditioning, acquisition, and analysis. In addition, several real-world examples of machine vision and computerized motion control are presented, to illustrate the practical applications of these technologies within the biomedical field.

Steps to Success Using Machine Vision

This section introduces three simple steps (Figure 92-1) that help one to achieve success with machine vision. The three steps to machine-vision success are as follows:

1. **Conditioning:** The process of preparing the imaging environment. One must consider factors such as lighting and motion, as well as the specific feature(s) of the objects being observed.
2. **Acquisition:** The process of selecting image-acquisition hardware, a camera, and a lens. One also uses software to capture and display the image.
3. **Analysis:** Includes all of the image-processing steps one uses to answer questions about the image. Questions such as “How big is this object?” and “Is this object present in the image?” can be answered.

Other practical examples of machine vision and virtual instrumentation are discussed in the following three examples. The first example shows how a computer can read a seven-segment display and can display these “analog images” in the form of a digital indicator, as illustrated in Figure 92-2.

This next example (see Figure 92-3) shows how virtual instrumentation and machine vision can be used to read the position of a needle. These “virtual instruments” (VIs) are useful in many applications, such as the calibration of speedometers and gauges in the automotive and medical industries.

The last example (see Figure 92-4) illustrates how machine-vision applications can read standard barcodes. In this example, the user performs a simple calibration procedure by selecting a “region of interest” (ROI) that crosses the barcode area, and the VI then will automatically interpret standard barcodes into their numeric equivalents.

In the following, several real-world examples of biomedical applications that use machine-vision and/or motion-control technologies are presented.

Case Study #1: The EndoTester™—A Virtual Instrument-Based Quality Control and Technology Assessment System for Surgical Video Systems

The use of endoscopic surgery is growing, largely because it is generally safer and less expensive than conventional surgery, and patients tend to require less time in a hospital after endoscopic surgery. Industry experts conservatively estimate that about 4 million

minimally invasive procedures were performed in 1996. As endoscopic surgery becomes more common, there is an increasing need to evaluate accurately the performance characteristics of endoscopes and their peripheral components.

Introduction

The assessment of the optical performance of laparoscopes and video systems is often difficult in the clinical setting. The surgeon depends on a high-quality image to perform minimally invasive surgery, yet assurance of proper function of the equipment by clinical engineering staff is not always straightforward. Many variables in the patient and equipment may result in a poor image. Equipment variables, which may degrade image quality, include problems with the rigid endoscope, either with optics or light transmission. The light cable is another source of uncertainty because of optical loss from damaged fibers. Malfunctions of the charge-coupled device (CCD) video camera comprise yet another source of poor image quality. Cleanliness of the equipment, especially lens surfaces on the endoscope (both proximal and distal ends), is a particularly common problem. Patient factors make the objective assessment of image quality more difficult. Large operative fields and bleeding at the operative site are just two examples of patient factors that can affect image quality.

The evaluation of new video endoscopic equipment is also difficult because of the lack of objective standards for performance. Purchasers of equipment are forced to make an essentially subjective decision about image quality. The authors have developed an instrument, the EndoTester™ with integrated software to quantify the optical properties of fiberoptic endoscopes. Figure 92-5 illustrates the main menu of this application.

Materials and Methods

The EndoTester™ is a specialized optical bench used for the quantitative testing of the fiber-optic path and the lens system in rigid and flexible endoscopes. In addition to the specialized test station, the EndoTester™ requires the following:

- A high-intensity variable light source
- A flexible fiber-optic cable
- A CCD video camera processor
- An optional video monitor (recommended)
- A standard PC and a video-capture board
- Laser Printer (600 dpi or higher recommended)

A standard PC containing either an 8-bit grayscale or a 24-bit color video digitizing board (MRT Videoport, MRT Micro, Inc, Boca Raton, FL or IMAQ-PCI-1408, National Instruments, Austin, TX) and custom software allows for easy acquisition and analysis of the endoscope’s optical properties. Collectively, the optical test bench and specialized software allow the user to perform a series of tests on the endoscope and its peripheral devices. Specifically, these tests include the following:

- Relative light loss
- Reflective symmetry
- Percent of lit (i.e., good) fibers
- Geometric distortion
- Modulation transfer function (MTF)

Each series of tests is associated with a specific endoscope to allow for trending and easy comparison of successive measurements. Specific information about each endoscope (e.g., manufacturer, diameter, length, tip angle, department/unit, control number, and operator), the reason for the test (e.g., quality control and pre/post repair) and any problems associated with the scope are also documented through the electronic record. In addition, all quantitative measurements from each test are automatically appended to

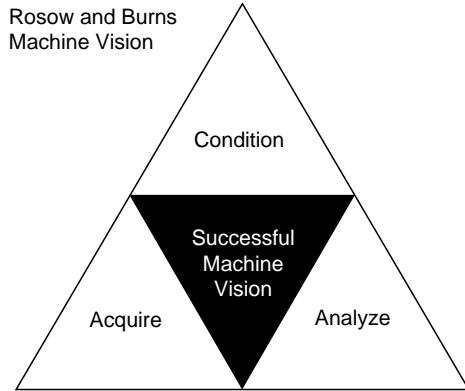

Figure 92-1 Three steps required for successful machine-vision applications. (Courtesy of National Instruments).

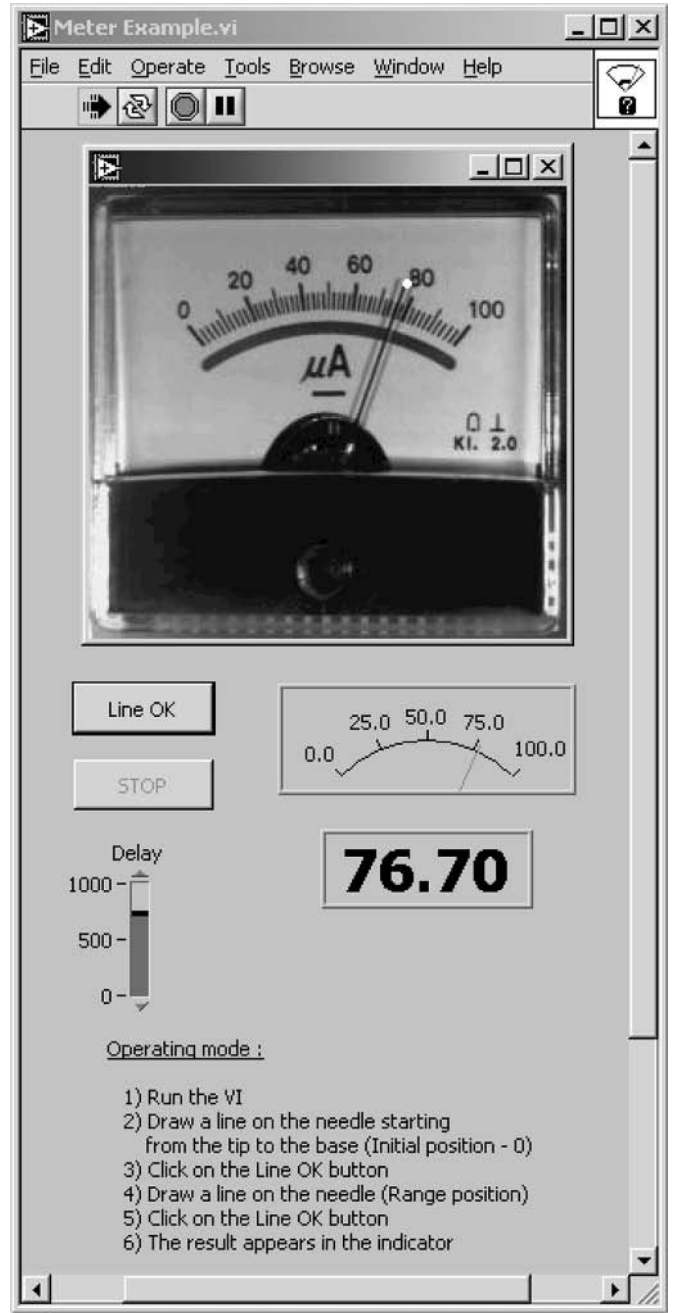

Figure 92-3 Meter example.

Figure 92-2 Seven-segment LCD example.

the electronic record. Figures 92-7 and 8 illustrate the information profile and problem-entry screens of the EndoTester.TM Figure 92-9 illustrates the test sequencer, in which the various tests can be selected either manually or automatically.

Endoscope Tests

Relative Light Loss in Optic Fibers

The relative optical light loss measurements quantify the degree of light loss from the light source to the distal tip of the endoscope. The relative light loss will increase with fiber-optic damage. Changes in the light-source intensity or the condition of the fibers in the fiberoptic cable are normalized out of the relative loss calculation because the relative light loss is determined directly from the endoscope's light output and light input.

Having a simple means to quantitatively measure performance variation with respect to time is desirable for all endoscopes but appears to be particularly valuable for the evaluation of disposable endoscopes. These units can be projected to have a rated life of 30 uses, but measurements of performance change under actual operating, and sterilizing conditions at a given institution support periodic quantitative measurements.

Figure 92-4 Barcode example.

The relative light loss for the optic fibers of the endoscope under test is calculated by the following equation:

$$\text{Relative Light Loss} = 10 \log \left(\frac{\text{Light Out}}{\text{Light In}} \right)$$

The “light in” value is measured by configuring the output-connection end of the fiberoptic cable to a test fixture that holds the cable a fixed 2-inch distance from a photometer (Edmund Scientific, Model INS-DX100). The “light out” value is measured by the photometer illuminated by the endoscope under test.

Reflective Symmetry

“Reflective symmetry” is a measure of light amplitude in the endoscope’s field of view. This value is important in that it quantifies the effective distribution of light.

By employing five magnitude comparators, it is possible to transform the continuous illumination pattern into five annular rings of decreasing grayscale. The pattern of gray rings produced by this test should be nearly centered on the image. The pattern is circular for zero-degree endoscope tip angles and sometimes is elliptical for angled endoscope tips. A histogram graphs the number of pixels from each comparator output (light intensity). For each “ring” that is displayed in the filtered image, the user can see graphically how many pixels exist for each band of intensity. In order to pass this test, the “percent bright area” is required to be greater than or equal to 50% of the maximum brightness. The following equation defines how percent bright area is calculated. “Gray 1” and “Gray 2” refer to the two brightest (i.e., innermost) rings.

$$\text{Percent Bright Area} = \left(\frac{\text{Gray 1} + \text{Gray 2}}{\Sigma \text{ pixels}} \right) \times 100$$

In addition to calculating the percent bright area of the field of view, the “boresight error” can be measured. The boresight error is defined as the difference between the center of the field of view and the center of illumination provided by the endoscope. A grid of 0.2-inch × 0.2-inch squares, whose center square is solid black, is positioned in the center of the field of view. Combining this grid with the ring pattern shows the geometrical distance from the center of illumination to the center of the field of view. By counting the 0.2-inch square grid, a quantitative measure of the boresight error is determined for the endoscope at a 2-inch tip distance.

Lighted Fibers

A close-in reflection (less than 0.25 inch separation) of the distal end of the endoscope from a polished mirror or lucite surface is captured by the CCD camera. This provides a record of the pattern of lighted optical fibers for the endoscope under test. The number of lighted pixels will depend on the endoscope’s dimensions, the distal end geometry, and the number of failed optical fibers. New fiber damage to an endoscope will be apparent by comparison of the lighted fiber pictures (and histogram profiles) from successive tests. Statistical data are also available to calculate the percentage of working fibers in a given endoscope.

In addition to the two-dimensional profile of lighted fibers, this pattern (and all other image patterns) can be displayed in the form of a three-dimensional contour plot, as shown in Figure 92-12. This interactive graph can be viewed from a variety of viewpoints in that the user can vary the elevation, rotation, size, and perspective controls.

Geometric Distortion

The geometric distortion test is used to quantify the optical distortion of the rod-lens system. The EndoTester’s video frame grabber captures the image of a square grid pattern. “Distortion” is defined as the change of magnification at points around the field of

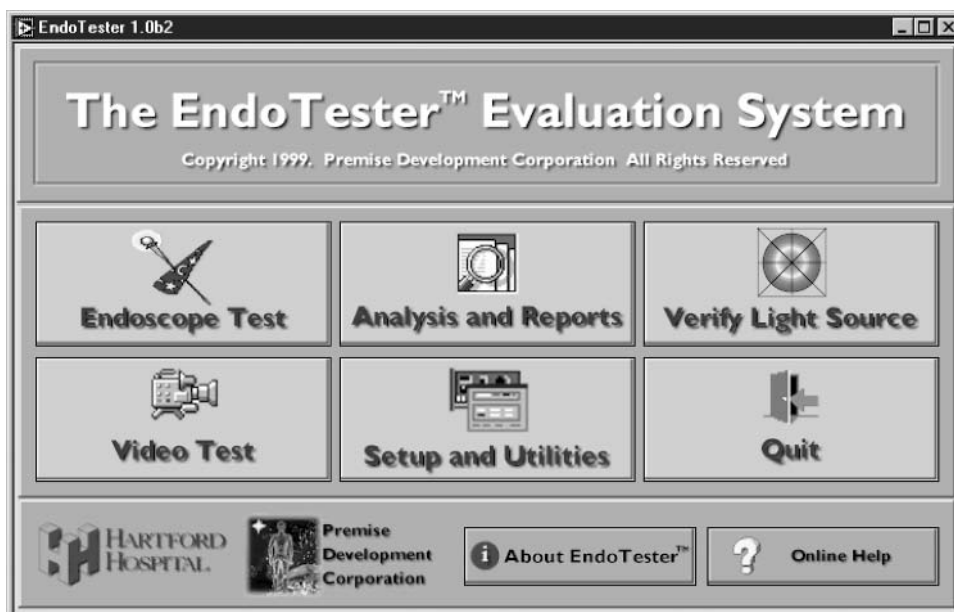

Figure 92-5 The EndoTester™ main menu.

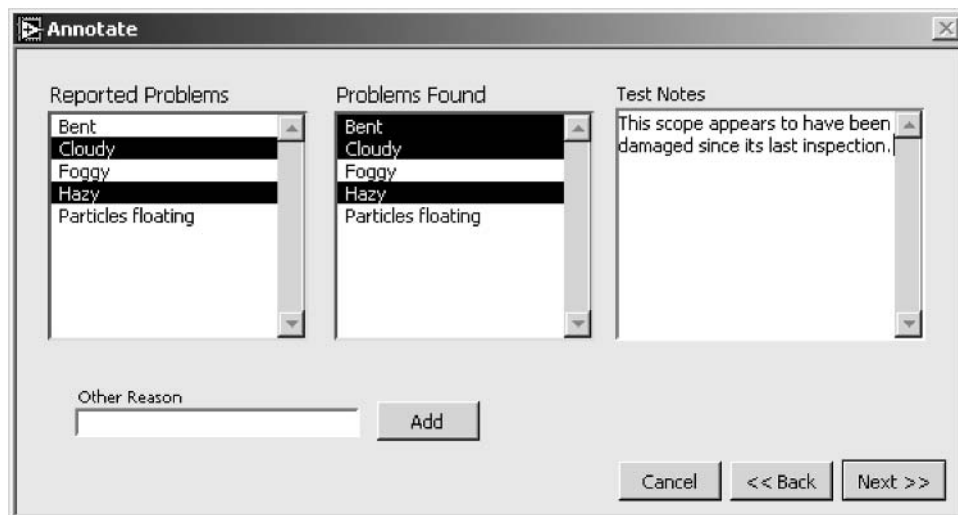

Figure 92-8 Problem-entry screen.

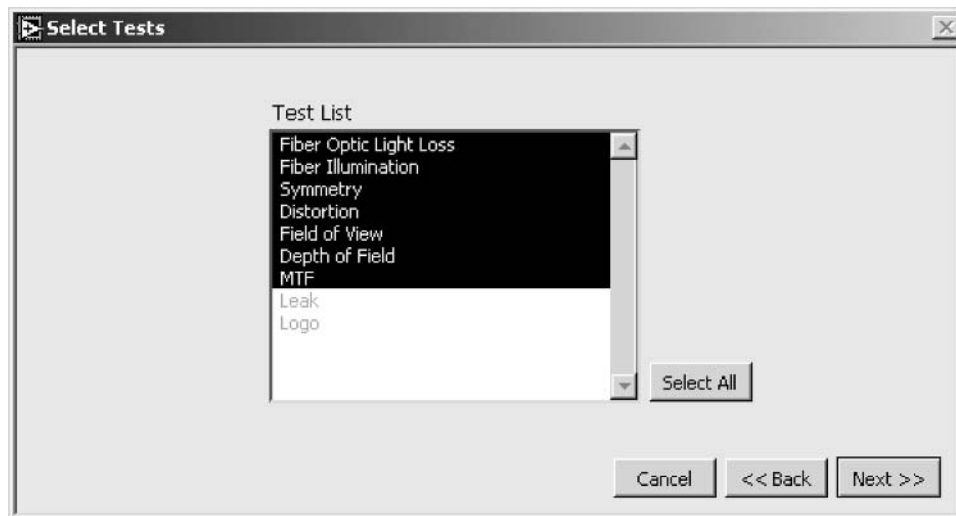

Figure 92-9 EndoTester™ test selection.

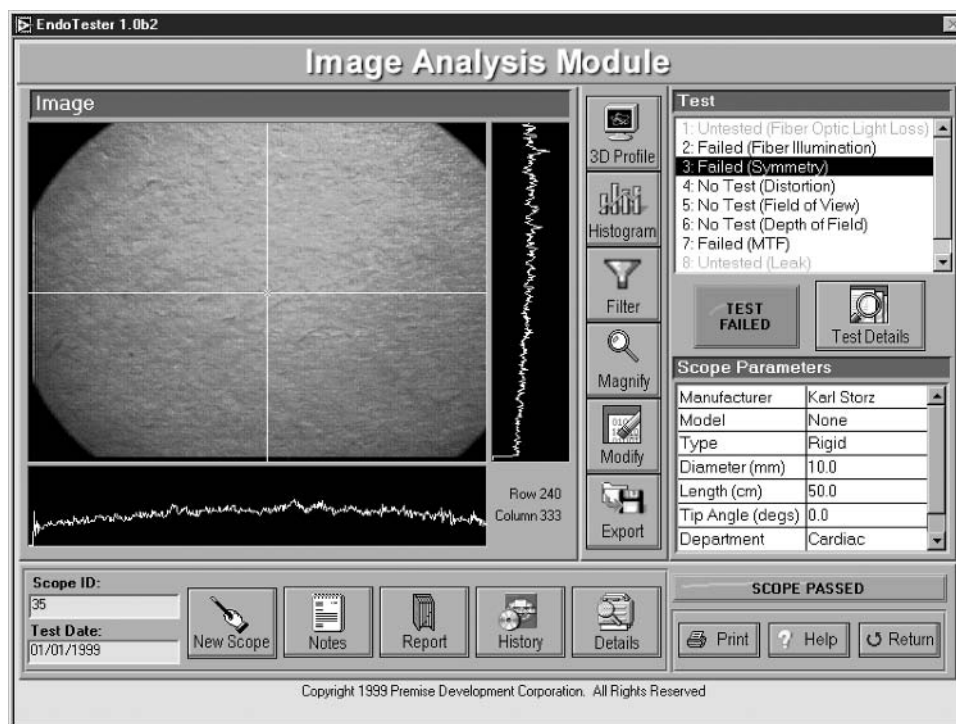

Figure 92-10 Reflective symmetry test.

view with respect to the maximum magnification occurring at the center of the field of view. By measuring the diagonal length of the central square of the pattern, with respect to the diagonal length of any other square, the geometric distortion can be determined. The percentage of distortion is calculated by the following equation:

$$\text{Percent Distortion} = \left[\left(\frac{\text{Other Square Diagonal Length}}{\text{Central Square Diagonal Length}} \right) - 1 \right] \times 100$$

Figure 92-13 illustrates the screen that is used to measure the geometric distortion of the endoscope under test.

Modulation Transfer Function

Aperture response is a universal criterion for specifying picture definition and other aspects of imaging system performance. It can be used for film images, camera lenses, television camera imagers, receiver picture tubes, and the human eye. The aperture response is measured as a contrast ratio by a square-wave pattern (contrast transfer function [CTF]) or a sine-wave pattern (modulation transfer function [MTF]).

The square-wave response data can be converted to equivalent sine-wave data by mathematical manipulation; however, the sine-wave method is the most direct approach. Variable density film targets are now available as sine transmission targets; hence, a direct measurement of MTF can be performed. In fact, even a single-space frequency measurement can provide a good index of performance for an optical lens system such as an endoscope. This is the approach used by the EndoTester.™ The

endoscope is tested with a one-cycle-per-millimeter sinusoidal transmission target (Sine Patterns, Penfield, NY).

The MTF of the lens system is measured at a spatial frequency of six cycles per degree of apparent field of view. Measurements at this frequency are considered to be accurate indications of good optical instrument performance, when the MTF is high. Thus, a single spatial frequency on the test target provides a good quantitative index of the local spot performance of the endoscope's lens system. Typically, the center region of a lens has the best optical performance, and the edges of the lens have less visual sharpness. Therefore, the MTF test measures performance at the left and right edges, the top and bottom edges, and the center of the lens. Studies have shown that a user's perception of image quality can be correlated to high values of modulation transfer function.

The MTF tests use a film target whose transmittance of white light varies sinusoidally across the X-axis and is constant with respect to the Y-axis. The fiber-optic cable is removed from the endoscope under test and is used to illuminate the sine target. The endoscope views the transmitted sinusoidal light pattern. The frame grabber captures the sinusoidal light variation along the horizontal sweep axis of the television image of the target.

"Modulation" is defined as:

$$\text{Modulation} = \frac{(T_{\max} - T_{\min})}{(T_{\max} + T_{\min})} \text{ Where T is transmitted light intensity.}$$

When this measurement is made over a range of spatial frequencies, a plot of the curve of the modulation transfer ratio as a function of spatial frequency is called the "modulation transfer function" (MTF). The MTF of a system is equal to the product of the MTFs

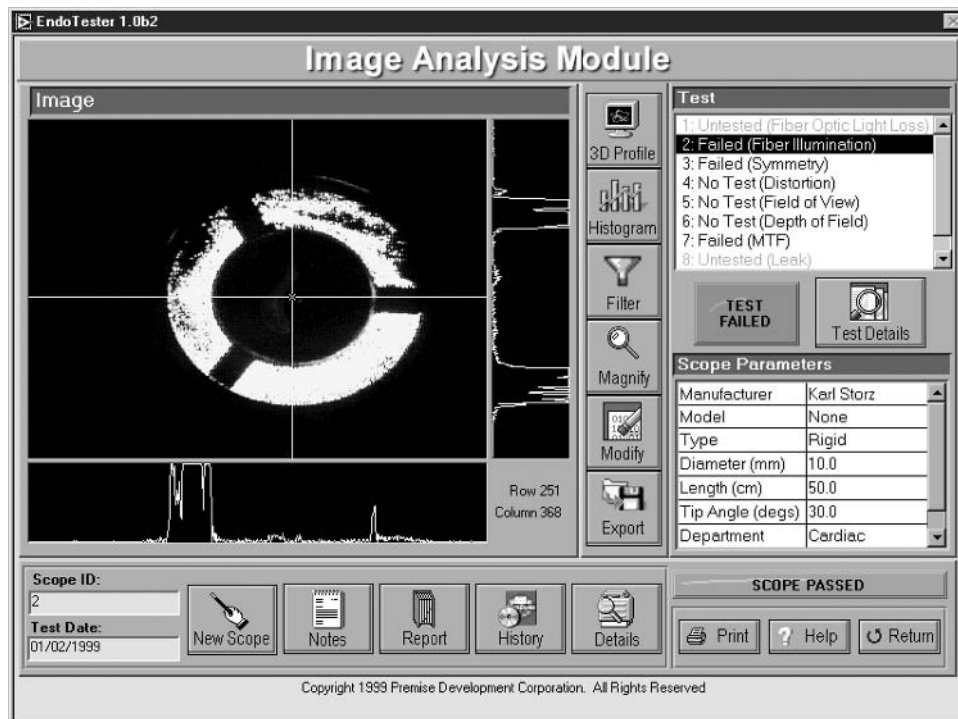

Figure 92-11 Endoscope Fiber Illumination Test.

Figure 92-12 Endoscope fiber Illumination (3-D contour profile).

of each component of the system. Thus, the MTF of the signal captured by the frame grabber is the product of the endoscope's MTF and the TV system's MTF. Figure 92-14 illustrates the screen that is used to measure the modulation transfer function of the endoscope under test.

Discussion

An easy-to-use optical evaluation system for endoscopes has been developed. This system allows objective measurement of endoscopic performance prior to equipment purchase and in routine clinical use as part of a program of prospective maintenance. Measuring parameters of scope performance can facilitate equipment purchase. Vendor claims of instrument capabilities can be validated as a part of the negotiation process.

The adoption of disposable endoscopes raises another potential use for the EndoTester™. Disposable scopes are estimated to have a life of 20–30 procedures. However, there is no easy way to determine exactly when a scope should be “thrown away.” The EndoTester™ could be used to define this end-point.

The greatest potential for this system is as part of a program of preventive maintenance. Currently, in most operating rooms, endoscopes are removed from service and sent for repair when they fail in clinical use. This practice causes operative delay with attendant risk to the patient and an increase in cost to the institution. The problem is difficult because an endoscope might be adequate in one procedure but might fail in the next, which might more exacting because clinical variables such as large patient size or bleeding. Objective assessment of endoscope function with the EndoTester™ could eliminate some of these problems.

Equally as important, an endoscope evaluation system also will allow institutions to ensure value from providers of repair services. The need for repair can be better defined,

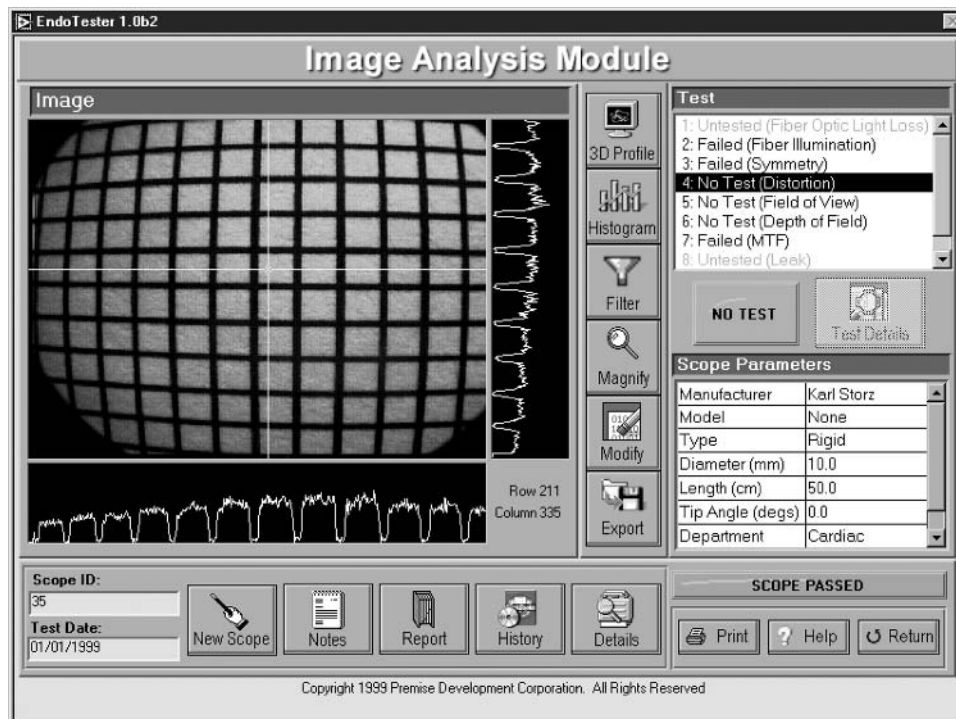

Figure 92-13 Distortion-analysis panel.

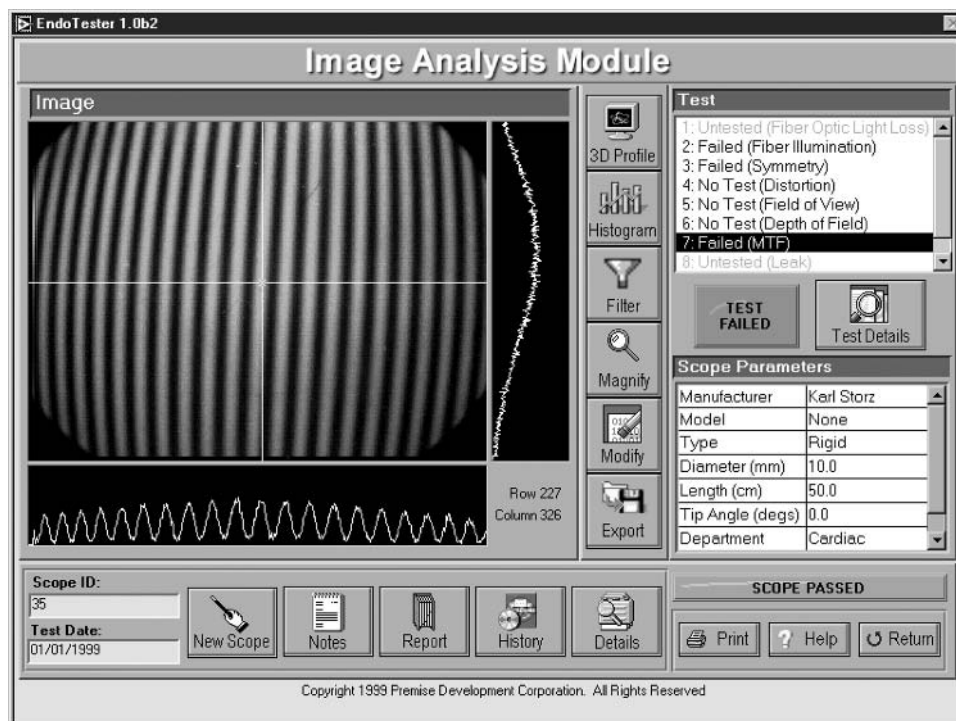

Figure 92-14 Modulation transfer function.

and the adequacy of the repair verified, when service is completed. This ability becomes especially important as the explosive growth of minimally invasive surgery has resulted in the creation of a significant market for endoscope repairs and service. Endoscope repair costs vary widely throughout the industry, with costs ranging from \$500 to \$1500 or more per repair. Inappropriate or incomplete repairs can result in extending surgical time by requiring the surgeon to “switch scopes” (several times, in some cases) during a surgical procedure.

Given these applications, the authors believe that the Endo Tester™ can play an important role in reducing unnecessary costs, while at the same time improving the quality of the endoscopic equipment and the outcome of its utilization.

It is the sincere hope of the authors that this technology will help to provide accurate, affordable, and easy-to-acquire data on endoscope performance characteristics, which clearly are to the benefit of the health care provider, the ethical service providers, manufacturers of quality products, the payers, and of course, the patient.

Case Study #2: A LabVIEW-Based Wound Measurement System

Description of System

The wound management system is a simple, portable, computer-based approach to wound assessment that implements both digital and infrared imaging technology. The digital image is analyzed to determine wound area and color properties, while the infrared image will be analyzed to determine blood perfusion properties of the wound.

The purpose of the wound management system is to provide a simple and cost-effective method by which health care personnel can quantify the healing rate of a wound, assess the effectiveness of wound care treatment techniques, and document wound healing progress. The computer-based system improves the repeatability and effectiveness of both

wound area measurement and wound coloration analysis as compared to current practices.

Current Wound Management Practices

Wound measurements currently involve invasive and inconsistent measurement techniques that utilize manual measurement tools or plastic wound overlays and require estimation of wound size using geometric simplifications (e.g., considering only the length and width of a wound and using a square area approximation of wound size). Current practices also involve qualitative, subjective clinician assessment of wound colorization and inconsistent use of photographs to document patient progress.

Wound care currently encompasses a wide variety of patient types, from acute, simple lacerations seen in the emergency room; to devastating wounds resulting from trauma and surgical interventions; to chronic, lower extremity ulcers and pressure sores. There is fragmentation of wound care personnel and facilities within the medical community. Currently, new treatment modalities are appearing at a rapid rate. It is often beyond the ability of a single individual to comprehend and incorporate the new information into improved and cost-effective techniques for patient care.

Chronic wounds represent a major issue in health care today, particularly among the elderly. Nonhealing wounds can persist for years, causing pain to patients and placing them at risk for secondary infection or loss of limb. The financial burden of the care of these patients is phenomenal: Institutional care of nonhealing wounds is estimated to cost approximately \$1000 per day. A recent study estimates that approximately eight million people in the United States currently suffer from nonhealing wounds, resulting in over \$10 billion in additional annual health care costs.

As a result, wound care has become a specialty in itself. Over the last 15 years, an enormous number of wound care products and services have emerged, claiming to empower clinicians with the ability to manage the healing process effectively. In addition, several "wound measurement" products have been introduced to the market. These products range from simple rulers and pliable transparent sheets (with "bull's eye" target patterns) that cost less than \$20, to high tech, computer-based measurement systems that cost over \$80,000.

Several factors recently led to the emergence of wound care as a distinct medical discipline. Dedicated wound care programs are increasingly caring for Americans who suffer chronic wounds, and they offer the potential to produce enhanced outcomes at reduced costs for payers and consumers of health care services. Evidence of this trend can be found in a variety of recent reports and studies. A report by Frost and Sullivan indicates that the United States wound-management products market is now \$1.74 billion and that it should grow to \$2.57 billion by 2002. The cost of treating the chronic wound is estimated at \$5 billion to \$7 billion per fiscal year, and these wounds are increasing at a rate of 10% per year, according to the report. (For more information, see <http://www.pslgroup.com/dg/daf6.htm>.)

The development of the American Academy of Wound Management (AAWM), a national, nonprofit certifying board is another indication that wound care is coming into its own as an industry. Board certification is now available for physicians, nurses, therapists, researchers, and other health care professionals involved in wound care. Over 1000 wound care professionals have requested applications for board certification through AAWM.

Advantages of System

In most hospital settings today, the daily clinical routine for wound care involves little or no quantitative documentation. Measurements are performed generally with the help of a ruler or a disposable transparency onto which the wound is drawn. In some cases, clinicians will periodically take pictures with a digital camera, but no formal protocol has been established, no lighting considerations are taken into account, and the purpose is more educational and qualitative than quantitative. Figure 92-15 illustrates examples of current tools and techniques that are used to measure wounds and healing rates.

The LabVIEW-based Wound Management System eliminates subjectivity and approximations by using computer algorithms to: Calculate the wound area based on the true, irregular wound outline; determine the percentage of wound area that is red, yellow, and black (the colors most indicative of wound healing progress); and evaluate or present information on wound vascularization (via infrared imaging). In addition, because the system is based on obtaining successive images of the wound as treatment progresses, clinicians have access to an image archive of patient progress. Clinicians

also can add personal notes to the file for a patient to create an inclusive database of images, analysis, and clinical progress. The system has been designed to be portable and easily used by a typical clinician. The system will be self-contained and will utilize a fixture to address concerns such as lighting, distance from camera to patient, and photographic angle.

Indicated Population

The applicable patient population includes sufferers of acute wounds (e.g., lacerations, trauma, and surgical wounds) and chronic wounds (e.g., arterial, venous, and diabetic ulcers, and pressure sores) Application of the wound healing system will focus on the chronic wound population, which accounts for the most extensive costs to health care and would result in the most patient benefit. Initial proof-of-concept testing occurred at Hartford Hospital's foot clinic, which focuses on diabetic foot ulcers.

Figures 92-16, 92-17, and 92-18 illustrate some of the image acquisition, analysis, and data management modules of the wound measurement system.

Benefits of Wound Management Technology

The benefits of wound management technology can be divided into three primary categories: Benefits to the clinician; benefits to the patient; and benefits to the health care organization.

Benefits to the Clinician

- Consistent and repeatable method for measuring wounds
- Objective and quantitative data for assessing wound care approach
- Access to historical data on wound healing rates based on treatment type and patient-specific variables
- Easily accessible image archive of patient progress

Benefits to the Patient

- Noninvasive wound measurement and assessment
- Reduced likelihood of nosocomial infection
- Enhanced client understanding of and participation in wound management (e.g., measured improvement and visual presentation of wound progress motivates continuation of proactive patient practices)

Benefits to Health Care Organization

- More rapid assessment of wound care effectiveness, thereby decreasing treatment time and related costs.
- Decreased time required by the clinician to document wound condition.
- Remote sharing of information between sites for teaching and/or collaborating.

Discussion

Wound care continues to present financial and human burdens to the health care community. Clinicians recognize the usefulness of wound images and tools for tracking wound progress, but they lack tools that provide valuable information while limiting impact on patient flow and clinical efficiency. Without quantitative methods to assess individual patients and available treatment methods, it is difficult to optimize treatment protocols and to minimize patient suffering. User-interface development tools provide user-friendly and highly configurable means of interfacing with vision-capture devices and turning the resulting images into clinically relevant quantitative data. Algorithms for evaluating wound size and appearance eliminate the qualitative nature of human perception and replace perception with numeric and graphical data that can be quickly assessed by the busy clinician and applied to the treatment of suffering patients. Eventually, an integrated wound-measurement tool can become part of a successful and financially competitive wound care program. These tools will allow doctors, physical therapists, and nurses to become more proactive in their approaches and to limit reactive measures and the associated recovery time with the resulting benefits being shared by the patients, clinicians, and the health care delivery system.

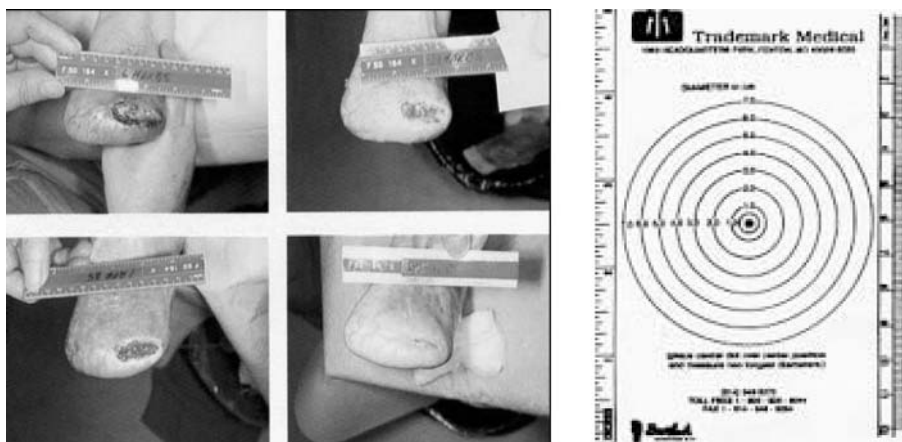

Figure 92-15 Wound documentation as it is ideally performed today. Source: Hartford Hospital, Hartford, CT.

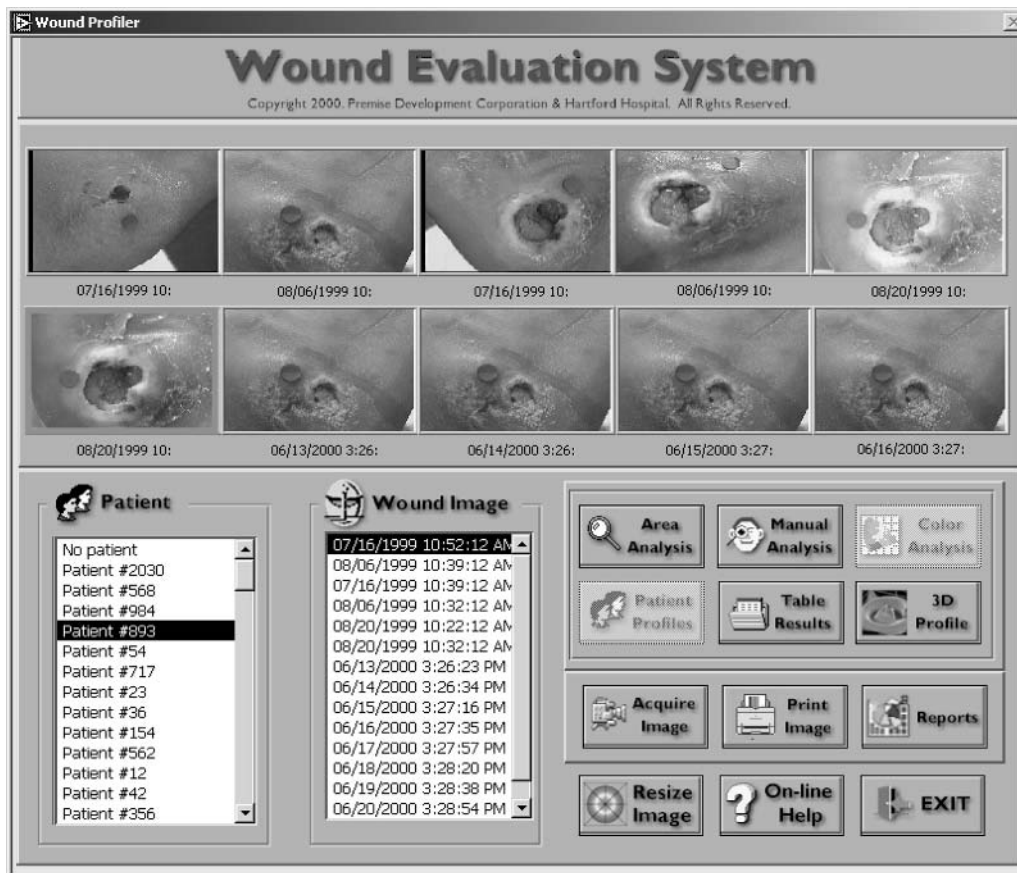

Figure 92-16 Patient and wound selection panel illustrates how any patient (and his or her respective wound images) can be selected for historical and visual comparison. In addition, a particular image can be selected for advanced analyses, as shown in Figure 92-17.

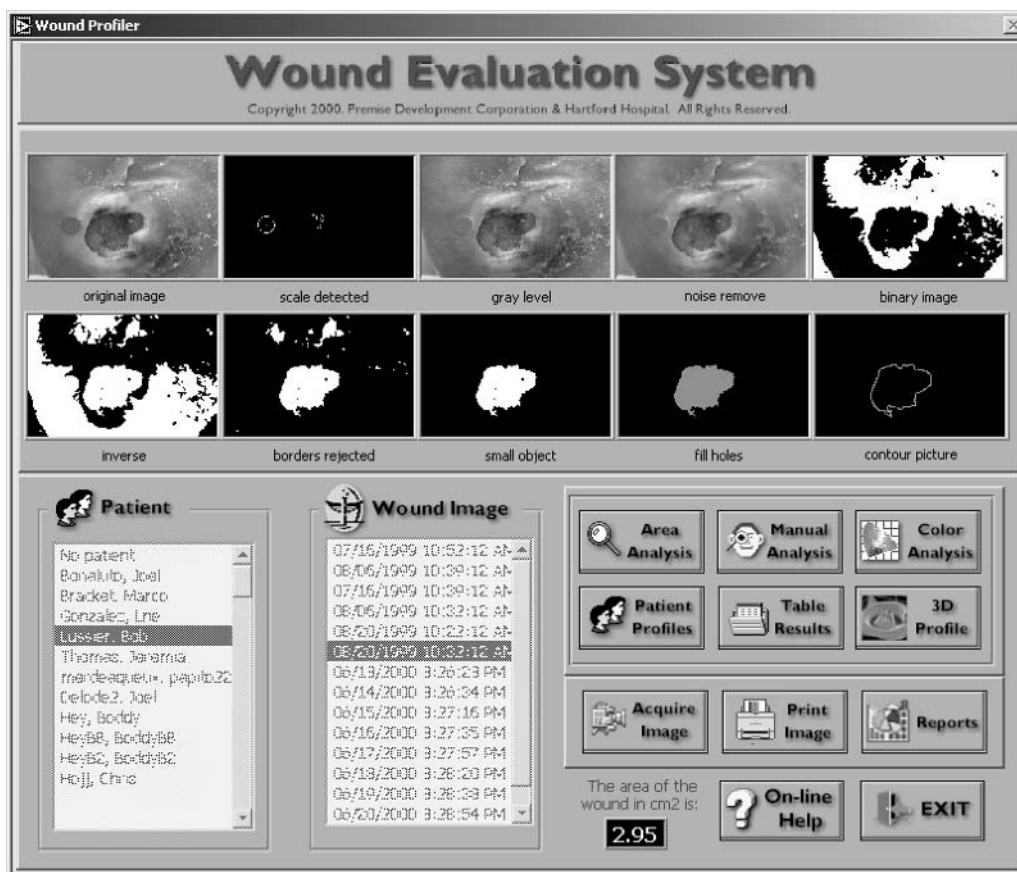

Figure 92-17 Automated wound analysis illustrates how a selected wound can be automatically analyzed in terms of its area and colorization. Computer algorithms are employed to identify the region of interest and to perform specific analyses including wound contour, area, and coloration. Analyses that are being developed include infrared imaging and volumetric analysis.

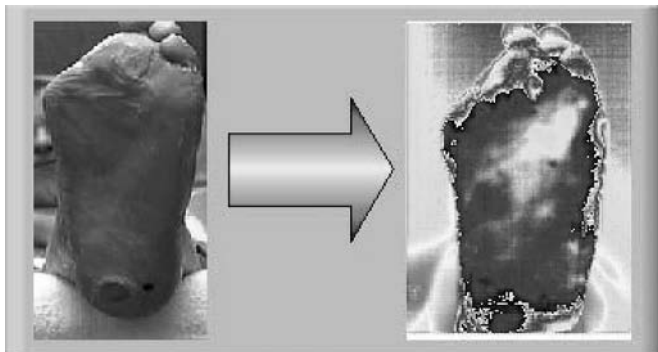

Figure 92-18 Infrared/thermal imaging. Example of thermal imaging on a diabetic foot wound. This technique can be an effective method to monitor wound healing and revascularization, as well as predict future wounds and ulcers.

Conclusions

Virtual instruments and executive dashboards allow organizations to harness effectively the power of the PC to access, analyze, and share information throughout the enterprise.

93

Perinatology is a specialty that involves the medical care and treatment of an infant and mother immediately prior to, during, and following childbirth. This time in most people's lives is the happiest time they will ever spend in a hospital. This chapter will focus on the environments and technologies experienced by mother and child before, during, and after birth.

The hospital labor and delivery (L&D) environment has changed considerably over recent years because of technological advances; however, most of the environmental changes in this area have been aesthetic. The aesthetic changes are the ones considered most comforting for the patients. The environmental changes associated with the neonatal intensive care unit (NICU) and pediatric intensive care unit (PICU) tend to be more general. However, given the focus on patient care, efficiency, and safety, these changes and redesigns are quite effective. In this case, the patient can be a child ranging from a premature infant to a young adolescent.

Gaining an understanding of the area and its function is much like understanding the schematics of a medical system or device. The various areas have defined floor plans. Thoroughly understanding associated patient flow is crucial in the planning, design, and implementation stages of an L&D unit. Once an understanding of the floor plan is gained, it is important to consider the required support areas. Just as important as the floor plan for the functionality of the area, the support areas of the given location are critical to provide effective and timely care to the patient. The individual room layout and configuration (even within the same department, such as L&D) can vary considerably. Furthermore, in addition to differences among individual patient rooms, the various clinical and support areas can vary as well. Within the various room layouts, the equipment orientation and storage is discussed.

The facility should be designed to support the varying services and equipment needs of each clinical area. The important and highly visible technology of infant security systems, their implementation, and integration into the existing facility infrastructure are discussed

The case studies discussed in this chapter illustrate ways in which various institutions have conceived and developed "user-defined" solutions to meet specific requirements within the health care and insurance industries. These dashboards support general operations, help hospitals to manage fluctuating patient census and bed availability, and empower clinicians and researchers with tools to acquire, analyze, and display clinical information from disparate sources. Decision makers can easily move from big-picture analyses to transaction-level details while at the same time safely sharing this information throughout the enterprise to derive knowledge and make timely, data-driven decisions. Collectively, these integrated applications directly benefit health care providers, payers, and, most importantly, patients.

Perinatology

Vinnie DeFrancesco

Clinical Engineer, Biomedical Engineering Department
Hartford Hospital
Hartford, CT

in this chapter. The complex interrelationship among data communications, clinical facility infrastructure, and medical device technologies is discussed as well. Medical gases and vacuum systems vary in the clinical areas, depending on the procedures performed in the rooms. Other utilities concerns are climate control and electrical power distribution.

The various medical device technologies in perinatology areas range widely in complexity and criticality. Their use depends on the needs of the patient and the clinical services provided (Schreiner, 1981). The medical technologies described in this chapter (e.g., monitors, radiant warmers, and ventilators) require technical support information for their effective utilization. Some emerging technologies discussed include the electronic medical record and advanced apnea-monitoring devices.

The Changing Environment of Childbirth

Until the early 20th century, childbirth was the domain of women. Pregnant women gave birth at home, generally with other women attending the birth. Anesthetics and pain medications were not used. By the 1940s and 1950s, women flocked to hospitals to give birth, under the care of male physicians. In the hospital, the common practice was to anesthetize women during labor to minimize or eliminate any pain during childbirth. The expectant father was relegated to the waiting room to shield him from the "gruesome reality" of childbirth. During that time in France, Dr. Ferdinand Lamaze developed "childbirth without pain" (now known as the Lamaze method) based on his observations of women in the Soviet Union giving birth without anesthesia. The Lamaze method gained popularity in the United States after Marjorie Karmel wrote of her childbirth experience using Lamaze in the 1957 book, *Thank You, Dr. Lamaze*. By the 1970s, "natural childbirth" was in vogue. Although most women continued to deliver in hospital settings, couples were

drawn to the Lamaze method. Women began to demand alternatives to the sterile hospital environment with its cold, hard delivery tables and stirrups. Eventually, many women and natural childbirth advocates regarded birth as a normal process that should occur in a warm setting with the family present. The consumer demand for change grew and resulted in changes in hospital practices. As natural childbirth was gaining recognition and popularity, physicians were making advances in pain management during labor. The development of the epidural anesthetic dramatically altered the birth experience for women. Suddenly, a woman could obtain pain control with drugs without losing alertness or awareness of the birth and without delivering a sluggish, "drugged" baby. Even women who required cesarean sections no longer had to have general anesthesia that deprived them of the awareness of the arrival of the baby. Many still regard natural childbirth as the ideal method, and the vast majority of women in the U.S. deliver in hospital settings. In addition, most men remain at their partner's side during delivery.

What has changed most recently in the hospital setting is the L&D environment itself. Hospitals have made great efforts to make the birthing experience occur in a warm setting with the family present. Today, the final stages of labor and the delivery occur in one room. In some cases, that room also serves as a recovery area. The L&D rooms have all of the necessary equipment for the birthing process while maintaining a pleasing appearance. Everything from the color scheme to the furniture creates a warm and peaceful setting, however, there is still the need to adhere to hospital standards. In the home, one does not have medical equipment (usually), medical gas outlets, or a bed with stirrups. Therefore, the challenge was to have these necessary resources available without significantly altering the environment. Interior designers and architects devised ways to hide the medical devices, as well as a method of retrieving them quickly when needed. Most of the equipment can be placed in cabinets located at the bed-head wall. Stirrups can be hidden under the patient's bed. The adverse effects of these aesthetic changes can cause the medical equipment to exceed operational levels, however. For example, a fetal monitor in a cabinet might overheat from lack of ventilation. The specifications on medical devices such as maximum operational temperature and heat output should be regarded well by architects who design the cabinetry.

The environmental changes for the NICU or the PICU have addressed the needs of their patients' normal environment. The general environments for children's hospitals have changed to be more suited for children. Designers and architects go to great lengths to look through a child's eyes, from a child's height. Their efforts focus on keeping children occupied to that they do not view a hospital as a bad or painful place. Great emphasis is placed on creating a quiet and peaceful environment with such devices as acoustical ceiling tiles and incandescent indirect lighting.

Patient Flow and Floor Plan

The patient's experience at the time of labor can be extremely hectic, even though the expectant mother and family have probably been preparing for this moment for the previous eight to ten months. An efficient and effective floor plan can be beneficial for the expectant mother, her family, and the hospital in general. The hospital has specific procedures that it must follow to provide the required support to deliver the newborn and ensure the well-being of the mother.

Prelabor, Labor, Delivery, and Postpartum

When the expectant mother first arrives at the hospital, she most likely will be sent to the admitting office, or to the prelabor area of L&D. The prelabor area generally comprises two separate sections: The admitting area and the patient room. The admitting area has a control desk where the clinical staff can monitor the expectant mother in her room while gathering patient information from the father necessary to complete the admissions process. In the prelabor patient rooms, the clinicians assess the expectant mother's true condition. The patient might experience contractions of the uterus that are actually "false labor" because they do not open the cervix as true labor does. At this point, the clinician can make the decision to admit the patient or to send her home. The physical location of the prelabor area should be relatively close to the emergency department/admitting office, or at least within a short walking distance. In most hospitals, the L&D rooms are adjacent to the prelabor area, because in most cases it would be the location where the expecting mother will give birth. The patient can bypass the prelabor area when the signs of labor are clearly present and can go directly to the L&D rooms, where she will go through labor and will deliver the baby. This area also may have a control desk where a clinical person will be present to perform the same duties as are performed in the prelabor area. The L&D area is usually in the center of all of the maternity areas, and the center of the L&D area is the clinical control area. This area is where most of the clinical staff will record and document the patient's progress through the labor process. The clinical staff also will assess and decide how the labor process is progressing and whether any intervention or pain medications should be administered.

Ideally, a practitioner decides for a cesarean birth if he or she ascertains that a surgical birth would be safer for the mother and the baby. A Cesarean birth is one in which the baby is removed through a surgical incision in the mother's abdomen rather than emerging vaginally. The cesarean birth is a surgical process that typically will occur in an operating room. Most hospitals have dedicated operating rooms for cesarean procedures or other operations that may arise during labor. As with any operation, the patient will be carefully monitored, and the surgical staff will be prepared for any emergency. The operating rooms are usually located adjacent to the L&D rooms for quick transport in case of emergencies. In a non-emergency situation, the preoperative procedures will be initiated calmly.

In an emergency, however, the preoperative period can be quite rushed and can appear chaotic as hospital personnel hurry to complete all of the necessary tasks rapidly. Commonly, some preoperative procedures are initiated in the mother's room before transfer to the surgical suite. Immediately after surgery, a woman typically will be wheeled to the recovery room, which usually is located in, or adjacent, to the operating rooms. Usually, a woman spends about one hour in recovery. Then, she is transferred to a room

in the postpartum unit. With changes in insurance reimbursement policies, most women spend only three days in the hospital after a cesarean section, and about two days after a vaginal birth.

Support Areas

Several crucial support areas should be considered when evaluating the patient flow and floor plan of an L&D unit. These include pharmacy, anesthesia workroom, clinical engineering, and equipment storage. During labor, contractions can cause much discomfort, which will cause patients to request pain medications. The doctor will select the most appropriate medicines, taking into account the medical condition of the mother and her baby. In the hospital, these medications are controlled and administered by a pharmacist and anesthesiologist. The anesthesia workroom is usually located in the same area as the operating rooms to facilitate anesthetics administration if necessary. A pharmacist will distribute the medications that the doctor chooses; these medications are usually analgesics. They are sometimes administered by injection to help relieve the pain associated with contractions. Typically, a pharmacy on the maternity unit consists of a medication station. Such a station can be a self-contained medicine-dispensing unit, which usually requires a key or code to access. These devices also will record and document the clinician who administers the medication, the time of administration, and the amount administered. In large maternity units, there may be more than one medication station. Clinical engineering's main responsibility is to create and implement an equipment management program to support the operation of the medical devices in the hospital, and it may have a satellite workroom on the maternity floor.

Although most of the equipment is located in the patient rooms, specialized and less frequently used equipment may be needed at times. An area should be allocated for storage of these infrequently used devices. The storage locations should be spread throughout the maternity area so that the clinical staff can gain quick access when they need to.

Individual Room Layouts

Prelabor and Postpartum

The patient room general requirements for the prelabor and postpartum room requirements are quite similar to each other. The requirements are the same for medical and surgical nursing units. The maximum room capacity is only two patients, with a minimum of 120 square feet of clear floor area for a double-occupancy room and 100 square feet for a single-occupancy room. For cesarean delivery suites, the minimum clear floor area is 360 square feet, and 300 feet for delivery rooms. The required clear floor area does not include toilet rooms, closets, lockers, alcoves, or furniture. There must be a minimum of three feet between the sides and foot of the bed, and a four-foot clearance is required in the case of multiple bedrooms. Each patient room that is intended for 24-hour occupancy is also required to have a window or vents that can be opened from the inside. Each room must be configured such that the patient can access a toilet room without entering a general corridor. One toilet room cannot serve more than four beds, and in new construction a hand-washing facility is required if a toilet room serves more than two beds. Hand-washing facilities for patient rooms most likely are located in patient rooms. The specification on medical gases and climate control are discussed below.

Labor and Delivery

In the equipment orientation for a typical L&D room shown in Figure 93-1, a fetal monitor is built into the cabinetry of the head wall unit, which is at the head of the bed. The suction and oxygen regulators are also located at the head of the patient's bed. In new L&D rooms, electronic charting systems are commonly found. With the same cabinetry at the head wall unit, a computer displays the electronic chart of the patient in the room, as well as that of other patients on the unit. Having these medical devices built into the cabinetry gives the room environment a warmer, more home-like look. However, one should be aware of ventilation and monitors' power requirements. Given that the room looks and operates quite differently when the equipment is in use, as opposed to when it is not in use, the flow of clinicians and patients must be evaluated in both scenarios. Moving in a clockwise direction, starting at the bed (Figure 93-1), one will see an infant warmer, in which the newborn is placed. The newborn also may require medical gases and suction. These utilities are built into the wall and typically are hidden by a painting when not in use. An entrance to a toilet room and hand-washing facility is located at the opposite end of the patient bed, as are a TV and VCR, which are built into cabinets. Lastly, a reclining chair that can be extended to form a bed is also provided for the patient's husband or any other person accompanying the mother at this time.

Nursery

The postpartum area of a maternity unit has the basic requirements as the Pre-labor and L&D areas. A hospital that has 25 or more postpartum beds is required to have a separate nursery to care continually for infants who require close observation. The minimum requirement for floor area is 50 square feet per bassinet or infant incubator. Most hospitals have replaced traditional nurseries with those in postpartum and labor-delivery-recovery-postpartum (LDPR) areas. These areas have the same minimum floor area, ventilation, electrical power, and medical vacuum and gases requirements as a full-term nursery does.

NICU and PICU

The NICU and PICU care for critically ill neonates and pediatric patients (Klaus and Fanaroff, 1979; Korones, 1981). These specialty intensive care units most provide for

Figure 93-1 A typical floor plan for a labor and delivery unit.

appropriate staffing, isolation, and safe transportation of the patients, along with life support from supporting hospital areas. A minimum of one airborne-infection control room with the ability for nursing observation is required. The number of infection control rooms is dependent on an infection control risk assessment. These rooms must be equipped with only one patient bed and its own toilet and hand-washing facilities. The rooms' walls, ceilings, and floors should be sealed tightly so that air cannot penetrate into the room from the outside. One of the major differences between a standard critical care unit and the PICU is that a sleeping space for parents must be provided in the PICU. In addition, a consultation/demonstration room in or next to the PICU must be available for private discussions between clinical staff and family. An examination and treatment room can be located centrally to serve the PICU or an adjacent area such as the NICU. The floor area must be a minimum of 120 square feet and must contain hand-washing fixtures, storage facilities, and a countertop or desk for writing. Some of the equipment in these treatment rooms might include patient monitors, incubators, and ventilators, all of which will be discussed later in the chapter.

In all these areas, a charting/recording and dictation room for the clinical staff must be allocated. The equipment to support these functions is becoming more sophisticated and integrated with the medical devices. For example, in many institutions, the traditional whiteboard used for charting the patient's progress has evolved to become an electronic whiteboard. These types of devices require additional infrastructure such as a network that communicates with the patient monitors in each of the patient rooms.

Facility Infrastructure

Security

In addition to the security measures that a hospital implements to ensure the safety of patients and visitors, most have installed added security measures in the maternity area. These security systems are specifically keyed to operate with the parents and the newborns, to ensure that the newborn leaves specific areas of the unit with only the parents or appropriate clinical personnel. Most systems operate using an electronic ID bracelet, which transmits a signal from the newborn to receivers located at entrance and exit points. Securing it to the infant or child's limb with the alarm band activates the transmitter. A display panel showing the floor plan of the unit designating the different locations or zones will visually and audibly inform the staff when an alarm has occurred. In addition to a display panel, a graphical display (usually with a print function) collects all transmitter data and displays the location and transmitter number of the infant or child involved. These control devices are placed at the control desk or centrally located room; they also are integrated into a main security panel at the hospital's security office. Some more sophisticated systems also can be connected to the elevators, causing them to bypass the floor, thus preventing egress by completely isolating the floor from the rest of the hospital.

Nurse-call systems are required for the maternity unit and the NICU and PICU. These systems ensure communication between individual patients in their rooms and a centralized location like the control desk. They also are used to communicate to staff from the patient rooms or the entire unit. For emergencies, pull-string-activated call boxes are located in the patient's toilet rooms for activating the nurse-call system at the control desk. For additional security, various areas of L&D install and integrate into the nurse-call system a video camera located at the entrance to the unit, which allows surveillance of those requesting admittance.

These types of systems require little preventive maintenance (PM). To ensure the operation of such security systems, a transmitter tester is required, to verify the operation of any transmitter with the sensors throughout the unit. This type of test can be scheduled annually. It is important to have available space, replacement circuit boards, control panels, and nurse-call boxes for immediate replacement in the event of a malfunction. The nurse-call system should be always active to ensure patient safety.

Data Communications

Data communications can be complex and difficult to implement, depending on the existing infrastructure of the facility. Although it is not a new issue in a hospital, it can be an infrastructure concern with the medical devices in the clinical setting. Most areas in a hospital use networks to integrate hospital/department applications for data collection and access to patient information. Manufacturers of medical equipment and, especially, patient monitors have created a data communication network to display patient data. The communication protocol between the devices has been the priority for the manufacture software application and is transmitted via a serial cable and RS-232 connector. Networks were created to collect real-time patient data from multiple devices and to display them in a centralized location. These data networks are installed in a hospital infrastructure specifically for these medical devices and exclusive to the rest of the hospital's data networks. Having these exclusive networks resulted in a secure and reliable network for real-time critical patient data. Because these devices are on an exclusive network and usually are proprietary, they cannot communicate with other applications and data unless these are provided by the same manufacturer using the same protocols. These systems are limited to a specific area, usually one critical care area with limited distance between the farthest two devices or nodes on the network. Most of the medical equipment manufacturers have adopted standard network protocols established by IEEE 802 standards (see Chapters 97, 98, and 102). This allows more integration with standard network hardware and other hospital systems and applications.

The protocol by which the medical devices communicate determines the infrastructure required. More and more, hospitals will need to grapple with the question of how medical devices communicate their data throughout the hospital reliably, rapidly, accurately, and securely, and how that information is to be integrated into the patient's electronic record, which will include such items as patient history, vital signs, and hospital and doctors' bills.

Climate Control

Relative humidity and ideal temperature requirements for most of the hospital are similar. The ventilation and filtration requirements vary throughout specific areas of the hospital. Table 93-1 shows the requirements for the clinical areas discussed in this chapter. For more detailed specifications and information on other clinical areas, please refer to

Table 93-1 Climate and control requirements for various clinical areas within a hospital

Location	Air movement relationship to adjacent area	Minimum outdoor air changes per hour	Minimum total air changes per hour	Recirculated by means of room units	Relative humidity (%)	Design temperature (degrees F/C)
Labor/delivery/recovery		2	2			70–75 (21–24)

the American Institute of Architects' *Guidelines for Design and Construction of Hospital and Health Care Facilities* or *Health Care Facilities Handbook* by The National Fire Protection Association (NFPA 99, 90A) guidelines.

Medical Gases and Vacuum

For all of the areas discussed in this chapter, such as L&D, postpartum, NICU, and PICU, the requirements for oxygen, medical air, and vacuum are the same. A hospital's piped gas and vacuum systems are categorized as a level-one system (by NFPA 99) because patients served by this system will be at the greatest risk should the system fail. The percentage of oxygen at the outlet should be 100% (+/- 2%). The static pressure (i.e., pressure at the outlet without any flow) for oxygen, air, and nitrous oxide (N₂O) should range from 40–60 pounds per square inch gauge (psig). Gas-flow pressure is drawn from the outlet at an increasing rate until flow reaches the test value of 100 liters per minute (lpm) or the pressure drops to within +/- 5 psig of the range noted earlier. The static pressure for vacuum (suction) ranges from 12 (minimum) to 31 (maximum) inches of mercury (in Hg). The PM for medical gas and vacuum systems consists of annual testing of pressures and flow rates and of vacuum (Frank, 2003). The typical repairs for these systems involve the outlets for the various medical gasses and vacuum or the device attached to the outlet, such as a suction regulator. Within each area, the required number of outlets for medical gasses and vacuum can vary greatly. The required number for outlets is shown in Table 93-2.

Power Distribution

All electric material and equipment, including controls and signaling devices, should comply with the electrical standards specified by National Fire Protection Association (NFPA). (see Chapter 109). Electrical standards should comply with applicable section of NFPA 70 and NFPA 99 (NFPA, 2000). The major concern for electrical standards is to prevent electrical hazards from failure within electrical medical devices or facility's electrical distribution systems.

One of the requirements for electric power distribution in L&D, NICUs, and PICUs is the provision of emergency power supplied by hospital-based generators. Specially marked (by, for example, a red outlet faceplate) emergency power outlets should be provided for life-support medical devices that must remain electrically powered in the event of a power failure. Medical devices integrated with a hospital-wide information system and data processing equipment should be on emergency power. Typically, emergency power circuits are energized within 10 seconds of loss of normal power. Most data processing systems, such as servers, will restart within that time. Systems that cannot tolerate power interruption for as long as 10 seconds must be energized by an uninterruptible power source (UPS).

Technologies

This section describes some of the electronic and electromechanical medical devices that a clinical engineer is likely to encounter in the service of perinatology. Only brief descriptions of the technologies are provided, and the reader is encouraged to delve further by consulting the references cited.

Neonatal Monitors

NICU and PICU monitors have many features in common with those used for adults in the intensive care units (Neuman, 1988a; Brans, 1995). Patient monitors have developed into a computer platform requiring sophisticated microprocessors and software (see Chapter 98). Some important specifications of which to be aware are performance specifications, network capabilities, interface capabilities, operating conditions, and support issues. Evaluating the processing and software capabilities of a monitor can be similar to evaluating those of a computer. One should evaluate the main processor speed and type of chip (e.g., Motorola® MPC860P (PowerPC), 66MHz). Also the graphical capabilities as determined by the graphics processor (e.g., 8-, 16-, or 32-bit). At a minimum, the monitor should have local area network (LAN) communication capability to communicate to a central monitoring device. A more sophisticated monitor will have a LAN Communication Processor (32-bit) that uses normal IEEE 802 standards. Some of the manufacturers are even using standard operating system software, which will make it easier to create comprehensive interfaces from device to device and from device to hospital information system. The typical power requirements are 110±20 VAC, 50/60 Hz, single phase and may average 100 W (max) power consumption. When installing monitoring

systems in a new or existing area, one should ensure that the heating, ventilation, and air-conditioning (HVAC) specifications for the room (e.g., ambient temperature, relative humidity, and air exchanges) can support the operation requirements of the monitor(s) (Hynman, 2003). Heat dissipation is a critical monitoring parameter (measured in BTU/hr or watts) to consider when the room draws call for the equipment to be located in a confined space like a cabinet.

Support issues for patient monitors can become much more complex if the monitors are integrated through a network. A patient monitoring network can become another system that requires support for the hardware and software components that make up the network. If the manufacture uses proprietary communication devices and software, it will be more difficult to support the equipment without support from the manufacture.

A PM program for the monitors should follow the manufacture's suggestions. Specialized test equipment may be required, to perform the recommended tests of proper operation of the monitors. Monitors may have special connectors or cables that are proprietary to the manufacturer. The sole-source nature of these accessories usually renders them more expensive than those that can be obtained from second sources. This sort of information should be considered at the time of equipment evaluation and purchase as it can have a sizeable effect on the cost of operation (see Chapter 33 and Figure 93-2, showing bedside monitors on a radiant warmer on which a neonate is lying).

Maternal/Fetal Monitors

Maternal and fetal monitors (Neuman, 1988b) provide information on fetal heart rate, uterine activity, maternal blood pressure, maternal arterial blood oxygen saturation (MSaO₂), and maternal ECG (MECG). Early in labor or in prenatal examination, indirect measurement of the fetal heart is obtained utilizing ultrasound transducer technology. A beam of ultrasound from a transducer placed on the maternal abdomen is directed to the fetal heart. Motion of the heart causes a Doppler shift of the frequency of the impinging beam as it is reflected back to the transducer. The transducer receives the reflected signal and electronic circuitry detects any differences between the transmitted and received ultrasound frequencies. Differences in frequencies indicate detected heart motion. Periodicity of the motion is displayed as heart rate. This rate is printed on a strip-chart recorder. At the same time, uterine activity is typically detected, also indirectly, by a transducer (i.e., tocodynamometer), which is applied to the maternal abdomen and measures the relative strength of uterine contraction. Uterine activity is also recorded on the

Table 93-2 Medical gas outlet requirements for various clinical areas within a hospital

Location	Oxygen	Medical air	Vacuum
Labor room	1	1	1

Figure 93-2 A typical array of neonatal monitors and associated cables and leads mounted on a shelf on an overhead radiant heating lamp. Also shown are examination lamp, ventilator tubing, and air-oxygen flow control.

same strip chart. Comparing fetal heart rate variations with uterine activity gives the clinician information that helps him to determine the condition of the fetus (Spencer, 1991).

Ultrasound transducers are sensitive and easily damaged by shock and vibration, and they are not repairable. When projecting costs, the replacement cost of transducers must be taken into account. Many fetal monitors have a telemetry feature, which allows patients in labor to ambulate while the fetal heart rate and their uterine contractions are continuously monitored. This added feature requires installing a telemetry antenna field covering the L&D area. The telemetry transmitters and receivers will require additional PM and repair because they are often damaged by being dropped.

Direct sensing of heart rate and uterine pressures is done immediately before delivery, when direct access to the fetal scalp is achieved. Fetal-scalp electrodes sense the electrical activity of the heart, and intrauterine pressure transducers measure uterine pressure. To aid in the determination of the physiological status of the fetus and the mother, monitoring of the fetal and maternal arterial blood oxygen saturation is performed (see Figure 93-3).

Fetal monitoring systems can include the feature of electronically recording and archiving data. Manufacturers have expanded these types of applications to include an electronic whiteboard, where information pertaining to the patient and fetus can be displayed and documented during labor. At the L&D control room, a central station display may be present for staff to survey the maternal waveforms of all patients on the unit. Implementation and support of these types of systems requires knowledge of networks and servers.

Incubators

Infant incubators provide thermal support for the neonate (Perlstein and Atherton, 1988). Most incubators also incorporate means for controlling oxygen levels and relative humidity of the air the infant breathes. Microprocessors incorporated in most modern incubators assist in the accurate control of temperature, humidity, and oxygen levels while enabling such features as graphical data trending of the critical parameters controlled by the incubator. An incubator PM program should take into account the manufacturer's recommendations and should include measurement of sound levels, operating temperatures of humidifiers, and oxygen sensors. Servo-controlled oxygen and humidity delivery systems typically require unique calibrations to be performed during PM. In addition to calibration, humidifiers require periodic replacement of the air-intake filter.

Inadequate maintenance can result in incubators that are hazardous to the infant. Incubators are used for many years, during which time they are subjected to appreciable shock and vibration because most are mounted on casters and are moved about for cleaning and storage. In the past, mechanical stress has damaged temperature control mechanisms, which, in turn, have overheated infants, causing brain damage or death. Old incubators that have been relegated to storage can be placed back into service during a high census period (Figure 93-4). These semiretired incubators might lack necessary safety features and manufacturer-recommended upgrades or modifications and can pose serious risks to neonates. For example, on some older models, a missing heat shield can permit an infant to crawl over a hot air vent and thus suffer severe burns. Lack of maintenance results in the use of incubators with high ambient-noise levels originating from defective or misaligned air-circulating fans, which can cause hearing loss. Defective door latches can enable an infant to crawl out of an incubator and fall to the floor (Dyro, 1977). Older incubators used mercury-based temperature sensors, which often broke, thus exposing the infant to hazardous mercury vapors (Dyro, 1981). It was not uncommon to observe a pool of mercury from broken thermometers and mercury switches on the floor of the heating compartment directly beneath the infant mattress.

Phototherapy Units

Phototherapy units treat hyperbilirubinemia by irradiating the baby with light in the blue region of the spectrum from 420–500 nm (Neuman, 1988a). This light oxidizes the bilirubin in the blood, thus producing compounds that can be eliminated from the body. The unit consists of a bank of 20-watt fluorescent lamps positioned 30–40 cm above the infant. Of concern is the lamp lifetime (typically averaging 1000 hours). Some phototherapy units incorporate an hour-meter to record bulb life and infant-treatment time. In order to maintain irradiance levels (measured in $\text{w}/\text{cm}^2/\text{nm}$) at therapeutic levels, periodic measurement with a photometer of irradiance at the infant surface is required. Figure 93-5 shows a stand-alone, moveable phototherapy unit. A bank of fluorescent lamps is housed in the overhead compartment. In use, the unit is wheeled to the neonate's bedside (either bassinet or incubator) and illuminated with the output of the lamps. Many radiant warmers have integral or accessory phototherapy units.

Ventilators

Figure 93-3 Fetal and maternal arterial blood oxygen saturation monitor.

Figure 93-4 Older incubators may be placed back into service.

The ventilator's main purpose is to assist the patient in breathing (Behbehani, 1995; Kirby et al., 1990). When used with neonates and pediatric patients, the ventilator must have sufficient flow range and sensitivity. The flow range is an important consideration for purchasing ventilators for use in an NICU and PICU. Typical inspiratory and expiratory tidal volume can range from 10–399 ml \pm 0.5ml for pediatric patients, and 2.0–39ml \pm 0.5ml for neonates. The flow-rate can range can be as sensitive as 0.00–3 l/s \pm 1%.

Ventilators are designed to provide the proper pressure flow range (0.1 ml/s – 3 l/s) for all hospital patients. The power supply requirements are standard, as for most medical equipment, although general battery backup devices are essential and should provide battery power for approximately 30 minutes. Additional features to consider with regard to power are hospital-grade twist-lock power plugs to prevent disconnection if the ventilator is accidentally moved. Ventilators require a medical gas supply that is free from water and oil, to ensure the proper operation. The amount of water in the air supply should be less than 5 g/m³, and the oil content should be less than 0.5mg/m³. The amount of water in the oxygen supply should be less than 20 mg/m³. Air and O₂ pressures should be in the range of 200–650kPa. The medical gas supply for the hospital should be tested prior to ventilator use. One should evaluate the hospital's standard on medical gas fittings so that the proper connectors for the ventilators can be purchased.

The proper support of these devices can be quite complicated and can require services from various hospital departments. Ventilators require proper cleaning according to the manufacturer's specifications between patients for infection control and proper operation. Most ventilators also require some type of calibration or operations check between patient uses. Supporting ventilators can be quite complex and time-consuming. A preventive maintenance program for ventilators should follow the manufacturer's suggestions. Test equipment is required for PMs and to ensure the proper operation of the ventilators. Ventilators require PMs to be performed on a time-in-operation basis (typically measured in hours; e.g., every 1000 hours of use). The PM requirements for the various hour intervals can vary depending on the manufacture. In many cases, PMs will require replacement parts. Parts that are required for the PMs can be purchased as a kit, and the price can vary depending on manufacture and model. The most typical parts can range from filters and O-rings to oxygen sensors. These requirements must be evaluated before purchase of ventilators, to properly plan for both infrastructure and operational cost in supporting ventilators.

Figure 93-5 Moveable phototherapy unit.

High-Frequency Oscillating Ventilators

The high-frequency oscillating ventilator (HFOV) is one of several high-frequency ventilators shown to be effective in the management of neonates in respiratory failure, especially those with severe barotrauma (Null et al., 1990). Other high-frequency ventilators include high-frequency positive-pressure ventilators, high-frequency jet ventilators, and high-frequency flow interruptors. HFOVs are capable of supporting the ventilatory and oxygenation requirements of neonates, full-term infants, and children who might be failing despite conventional ventilation. This type of ventilator uses a diaphragmatically sealed, electromagnetically driven piston, which is the main mechanical difference between the jet ventilator and conventional ventilators. For this type of ventilator, it is important to follow the manufacturer's suggestions on a PM program. Again, like the traditional ventilators, test equipment is required for PMs and calibration, to ensure the proper operation of the ventilators. The drive piston requires changing after it has performed a certain amount of cycles, as well as calibration every six months. The piston requires centering, which requires applying electrical counterforces to the piston coil, which maintains the piston centering. This amount of pressure can range from ± 130 cmH₂O, with an accuracy of $\pm 2\%$ of reading or ± 2 cmH₂O. The same specifications for medical gases, emergency power, and backup battery of the conventional ventilator apply to the high-frequency ventilator.

Inhaled Nitric Oxide Delivery Systems

The Inhaled Nitric Oxide (INOvent) delivery system is a delivery and monitoring system for inhaled nitric oxide therapy (Walding, 2003). The INOvent delivery system is not a stand-alone medical unit. It works in combination with a mechanical ventilator (or anesthesia machine) to deliver a constant concentration of nitric oxide (NO). The INOvent has its own comprehensive alarms to ensure safe and reliable operation with continuous monitoring of NO, NO₂, and O₂. Nitric oxide is supplied to the system by way of a gas cylinder. Both the gas and the system are highly specialized, heavily regulated, and available only through the manufacturer.

The INOvent is a highly specialized medical device. The manufacturer recommends that all repairs and PMs be performed by a specified, direct supplier company. The system does require a performance-verification procedure before using the unit on a patient. This performance verification includes bleeding and purging the head unit and the NO tanks

prior to operation or testing. Using a pressure gauge and a test circuit, one can perform various calibration tests to ensure proper operation.

Radiant Warmers

Most radiant warmers are integrated for L&D or LDRP areas of the hospital. Some new models of radiant warmers have changed with the environment of most LDRP rooms by incorporating such features as detachable wooden carts, which can blend into the aesthetics of the room. Some radiant warmers have pneumatic modules for resuscitation. Radiant warmers can be equipped with many options for measuring the newborn's temperature. The main function of the device is to providing radiant heat by way of infrared heating elements, which typically are mounted above the infant mattress. The output of these elements is regulated by a control mechanism that responds to infant skin-temperature information obtained from temperature sensors attached to the infant.

Figure 93-6 shows a radiant warmer termed "neonatal care station" by the manufacturer.

Radiant warmer technology has advanced over the last two decades, in part through the development of performance and safety standards (Dyro, 1977). Early versions of the radiant warmer had few of the safety features now incorporated into modern radiant warmers. While new, more effective, and safer technology exists, one must remain vigilant to control older technology that might be brought out of storage to address a high-census situation, as discussed above.

Care should be taken to ensure that temperature-sensing mechanisms are calibrated and that compatible temperature sensors are used. Incompatible sensors cause some radiant warmers to emit maximum heat output. Such uncontrolled maximum heat has burned infants (Dyro, 1977). The heater output should have a sensitive incremental adjustment, typically 10% of output. Inspections should include a check of infant containment mechanisms such as side panels. Defectively designed or worn latches have given way, thus enabling infants to fall off the mattress and onto the floor.

The pneumatic mechanisms give clinicians the capability to ventilate the neonate. They provide gas flow for a neonate and can operate with a gas blender to provide specific levels of oxygenation. Source gas pressures and flows affect performance and must be inspected periodically.

Apnea Monitors

Apnea monitors are part of the patient monitoring systems in the PICU and NICU (Neuman, 1988a). Some stand-alone apnea-monitoring systems are frequently used in the home for infants who have had apneic episodes in the hospital or who are at risk of apnea. (See Figure 93-7.) These incorporate heart rate monitoring as well as respiratory monitoring. Monitoring of breaths is typically done by transthoracic impedance monitoring. The same electrodes that are used to detect the ECG for heart rate monitoring are used to conduct a low-level, high-frequency (20-100 kHz) current through the infant. Breathing motions change the impedance, thus resulting in a voltage change detected by the monitor. When the monitor senses that breathing motions have ceased, it alarms after a delay of typically 20 seconds. The alarm alerts the care-giver to intervene. In many

Figure 93-6 Infant radiant warmer.

Figure 93-7 Transthoracic impedance apnea and heart-rate monitor.

cases, an apneic infant will resume breathing in response to slight tactile stimulation. In some cases, aggressive cardiopulmonary resuscitation is required.

Apnea monitoring is an imperfect technology in that all techniques that are used to detect breathing (e.g., transthoracic impedance, pressure sensors, airway temperature monitoring, pneumotachography, carbon dioxide sensors, and sound detectors) are susceptible to artifact, which can defeat the alarm system of the monitor. Dyro (1976, 1978) has described the hazards and risks of a wide range of apnea monitoring technologies. Environmental factors such as external vibrations from other devices and electromagnetic interference, and internal factors such as cardiogenic artifacts can cause the monitor to detect breaths when the infant is not breathing (Dyro, 1998).

Ultrasonic Scanners

Ultrasonic scanners use measure fetal age, gestational age, and fetal weight to obtain multiple ratio calculations, fetal biophysical profile, and twin gestational measurements and to generate reports. These are standard obstetric parameters that are usually incorporated into general ultrasound-imaging units (Goldberg et al., 1995). Computerized ultrasound units have specific programs and built-in ultrasound probes. Most machines allow for all fetal-growth data and ratio data to be stored on one 3.5-inch diskette for convenient data storage and retrieval and report printing.

A PM program for ultrasonic scanners should follow the manufacturer's suggestions. Required testing phantoms are required, to perform the recommended tests to ensure the proper operation of the ultrasonic scanner and probes. Replacement probes need not be repaired or purchased from the manufacture of the ultrasonic scanner unless they are specialized.

Future Technologies

The L&D, NICU, and PICU areas recognize the need to utilize an electronic medical record (EMR). The patient flow that was highlighted in the beginning of this chapter could be improved if all one had to do at the admitting office were to provide a card containing pertinent patient information. As patients progressed through labor, all vital signs, administered medications, and maternal parameter would be captured. For example, a maternity unit could request the acquisition of fetal monitoring data. If alarm conditions occurred, or if some type of intervention were necessary, (e.g., administration of medication), the information typically would be printed from the fetal monitor and retained. The fetal-monitoring data (e.g., heart rate variations and uterine contractions) also could be captured electronically and displayed on monitors, usually in the control room area. If a documentable event occurred, the clinician could make some type of indication on the fetal strip printout. Clinicians want the event to correlate to the correct time and fetal information on the fetal strip. Even though the fetal strip can be captured electronically, the information that the clinician dictates on the fetal strip cannot be. The department therefore keeps the printed fetal strips and electronic data documentation in the patient's medical record. A playback feature for the fetal monitoring recorded strips is needed, to document accurately the exact time an intervention was performed. The clinician then can play back the fetal strip to the point where a notation was required, without stopping the collection of new fetal-monitoring information.

Clinical engineering research and development has developed closed-loop monitoring systems. For example, traditional apnea monitors, after sensing apnea or low or high heart rate, trigger an alarm, which alerts the nurse to intervene. The nurse's first response would be tactile stimulation by hand contact, which often results in resumption of breathing. Providing a closed-loop monitoring method, a computer system can record EKG, heart rate, and pulse rate from a pulse oximeter to sense apnea. When apnea is detected, a signal is sent to a vibrotactile transducer, which can be placed on the neonate's thorax to stimulate breathing (Pichardo, 2003). The computer also can record the EKG, heart rate, and pulse rate of the neonate and correlated the data in the same time frame the stimulation was administered.

Conclusion

A wide range of varied and complex medical device technologies are utilized in perinatology. Opportunities exist for the clinical engineer to ensure that appropriate technologies are specified and acquired and, after purchase, to ensure that they are maintained in proper operating order. Research and development by clinical engineers can lead to improvements in existing technology.

Cardiovascular Techniques and Technology

Gerald Goodman

Assistant Professor, Health Care Administration,
Texas Women's University,
Houston, TX

There is perhaps no discipline of medicine that mimics electrical engineering as much as cardiology. From the study of electrical conduction for heart activity, to cardiovascular dynamics, the basic $E = IR$ equation applies. If one substitutes electron flow for blood flow, substitutes electrical resistance for vascular resistance, and views the heart as a power source, then one has the following: Cardiac output = (blood flow) \times (vascular resistance). In addition, cardiology may employ more electronic diagnostic technologies than any other medical discipline.

This chapter defines the medical specialty areas grouped under cardiovascular diseases, discusses the history of cardiovascular and cardiac technology as applicable to clinical engineering, and identifies future trends in this technology.

Definitions

In order to define and clarify this diverse field, one must first define the field anatomically. One can then define the medical specialties that typically practice on these organs and systems.

Anatomical Definitions

Thorax typically refers to the chest and lungs. Thoracic surgery can be any procedure in the chest cavity. However, it is typically associated with surgery on the heart or major arteries and veins.

Cardiac refers to the heart itself. Reference may be to heart muscle, heart valves, or other cardiac structures. The term *coronary* is tightly associated with cardiac disease (coronary artery disease).

Coronary is defined as “encircling in the manner of a crown.” It applies to vessels, nerves, ligaments, and other areas. For our discussion, “coronary” refers to that part of the coronary vascular system (coronary arteries) that serves the heart muscle.

Vascular refers to veins or arteries, or more generally, any specialized structure for conducting fluid. Within the terminology are several subcategories:

- **Cardiovascular**—relating to the heart and blood vessels (arteries, veins, and capillaries); the circulatory system.
- **Cerebrovascular**—relating to or involving the blood vessels in the cerebrum.
- **Peripheral vascular**—relating to the large blood vessels of the arms, legs, and feet.
- **Microvascular**—relating to the small blood vessels which lead to organs and nerves.

The adjective “cardiovascular” is typically used all-inclusively to describe diseases and treatments related to the heart and its associated circulatory system.

Cardiovascular Disease Medical Discipline Definitions

From the anatomical definitions come several major medical subspecialties for treating diseases of the cardiovascular system. The two major disciplines are cardiology and cardiovascular, or cardiothoracic, surgery. The distinction between the two is found in the term “surgery.” Cardiologists typically provide medical interventions, while cardiovascular surgeons provide surgical interventions.

Not all vascular diseases directly involve the heart. While the cardiologist, by definition, treats diseases of the heart and the cardiovascular surgeon performs surgery on the heart, each specialty must address diseases that can involve any part of the circulatory system. A cardiologist may diagnose and treat vascular disease as well as heart disease. Vascular surgeons may operate on the blood vessels only, while cardiovascular surgeons may operate on both the heart and associated vascular system. Typically, the two surgical specialty names are used interchangeably.

Cardiology has evolved into both a diagnostic and an interventional medical practice. Procedures that typically have been performed in the operating room by a cardiovascular surgeon, such as cardiac pacemaker insertions, may now be performed by the cardiologist in the cardiac catheterization laboratory (“cath lab”) (Lin, 1988). The technologies that are available to treat blockages in the coronary arteries, such as angioplasty (DeSciaccio and Cowley, 1988), can also be performed in the cath lab. Cardiologists who practice in this area are referred to as “interventional cardiologists.”

Cardiology has a subspecialty in the diagnosis and treatment of cardiac arrhythmias, which are variations in the electrical rhythm of the heart. An electrophysiologist specializes in the diagnosis and treatment of electrical conduction problems that cause arrhythmias.

Diagnostic Technologies for Cardiovascular Disease

The technologies used in the diagnosis and treatment of cardiovascular diseases are quite diverse. They include surgical interventions that physically repair diseased components of the heart (e.g., heart-valve replacement surgery), various surgical and nonsurgical techniques to clear artery blockage, and treatment with drug regimens to control such parameters as blood pressure and cholesterol level.

The discussion of technology is organized first by type of intervention, and then by location of use of the technology. Types of interventions are noninvasive and invasive diagnostic and surgical. Locations of use are office-based, cardiac cath lab-based, and operating room-based technologies.

Diagnostic Office–Based Noninvasive Technologies (Static Tests)

Diagnostic technologies for cardiovascular disease have evolved rapidly over the past ten years. The technology has focused on noninvasive diagnostic methods that reduce patient cost and patient risk. The primary classifications of diagnostic testing are static tests, stress tests, and ultrasound-based tests. All are office-based and typically are performed on an outpatient basis.

Static testing for cardiovascular disease refers to those tests that do not require the patient to exercise or otherwise physically alter their cardiac performance either during or immediately before a diagnostic test. Static tests include electrocardiograph and heart sound auscultation.

Electrocardiography

The electrocardiogram (EKG or ECG) is the basic assessment tool of cardiology (Clements and Bruijn, 1990). The technology uses surface electrodes placed on the chest of the patient (Neuman, 1998). Electrical activity of the heart—the electrocardiogram—is then reproduced on an oscilloscope-type display, and in a paper-chart recording.

While the physiology of the ECG is beyond the scope of this article, the essential facts are that the ECG represents the electromotive force generated by heart muscle (Berbari, 1995). These forces are represented as force vectors in the same manner as any force vector in engineering. The standard ECG technology uses multiple leads to record the vectors. Typically, a 12-lead view of heart electrical activity is reproduced simultaneously in a test that lasts less than one minute. Common technical problems in using an ECK machine include poor electrode adhesion, lead wire fractures, and background electrical noise (60-cycle electrical noise).

Phonocardiography

The phonocardiogram (PCG) detects and records heart sounds, the sounds made by the various cardiac structures pulsing and moving blood. The sound is caused by the acceleration and deceleration of blood and turbulence developed during rapid blood flow. The essential technology for listening (“auscultation”) to heart sounds is still the basic stethoscope. Electronic stethoscopes are available, but they have had little impact. Heart-sound auscultation is both a science and an art. The science of the sounds that relate to a specific

heart problem has been well established. The ability to discern the sounds or to recognize the sounds that are being heard is perhaps the art, although time-frequency techniques have been employed to analyze the phonocardiogram (Bulgrin et al., 1993).

Nuclear Source Testing

There are a number of cardiovascular static tests available that employ a radioactive source that is injected into the patient. These demonstrate damages and evaluate the function of the heart. As the injected radionuclide circulates to the heart, the presence of radioactivity in the ventricles of the heart or the myocardium is measured. Both planar and three-dimensional nuclear medicine are used in these studies. Single-photon emission computed tomography (SPECT) is a nuclear medicine technique that yields a three-dimensional reconstruction of the distribution of the radiopharmaceutical (Fahey et al., 1988).

Technetium-99m pyrophosphate scintigraphy is used to diagnose acute myocardial infarction at least 18 hours post-infarction. Areas of damaged myocardium contain calcium, which complexes with the Technetium-99m. Therefore, infarcted areas appear as hot spots.

Persantine thallium can be used for patients who cannot exercise. Persantine™ is the trademark for the drug dipyridamole, which is a coronary vasodilator. Persantine™ dilates normal coronary vessels more than the occluded vessels. Blood would preferentially flow to the normal vessels in a sort of "steal" phenomenon. A thallium scan can then reveal the ischemic areas by demonstrating reduced perfusion.

Diagnostic Office-Based Noninvasive Technologies (Stress Tests)

The diagnosis of cardiovascular disease may require the patient to physically alter their heart activity. The heart under stress from such activities as walking or running can give a clearer diagnostic picture than can a heart at rest. Although low, there are risks to stressing through exercise the heart of someone with suspected heart disease. Mortality was 0.5 per 10,000 in the United States and 0.2 per 10,000 in Europe in the late 1970s. Morbidity, primarily from ventricular tachyarrhythmias, is equally infrequent (Mukharji, 1988). Stress testing is performed under tightly controlled conditions, with continuous cardiac function monitoring, and with full cardiac resuscitation capability available. Conventional and nuclear stress testing are available.

Conventional Stress Testing

Stress testing can be accomplished with the patient walking or running on a standard exercise treadmill, with continuous electrocardiograph and blood pressure monitoring (Mukharji, 1988). Figure 94-1 shows a typical stress test system. Arrhythmias may appear during the exercise period or the resting period immediately after exercise.

Nuclear Stress Testing

Stress testing can also be accomplished in conjunction with the injection of a radionuclide. Thallium stress testing evaluates heart function by the observation of thallium distribution in the myocardium during exercise. Thallium is taken up by normal cells, in which case the scan shows an evenly distributed pattern of radioactivity. Areas of reduced blood flow (ischemic areas) induced by stress will appear as cold spots. In addition to the conventional equipment required for a stress test, the thallium stress test requires the use of a nuclear camera to record the thallium distribution. Because a nuclear source is being used, oversight by a radiation safety office that is certified for nuclear radiography is required (see Chapter 113).

Long-Term Trend Monitoring

The monitoring of cardiac activity during activities of daily living is a technique for capturing subtle arrhythmias (Tompkins, 1988). While not specifically a stress test, long-term monitoring does look at cardiac function under varying conditions of physical activity.

Figure 94-1 Stress-test system.

The patient wears the Holter monitor for a continuous 24- to 48-hour period (Holter, 1961). The monitor and technique are named after the late American biophysicist Norman Jefferis Holter. The monitor records a continuous electrocardiograph over this period. Monitors that can record blood pressure as well as electrocardiograph are also available. Older technology uses analog tapes for the recording. Newer monitors employ digitizing technology. In addition to the monitor, a scanner is necessary to decompress and analyze the recording. The output of the scanner typically includes a summary of events by arrhythmia type, and an actual electrocardiographic recording.

An advance to the continuous recording Holter monitor is an event monitor carried by the patient, and used only when the patient senses a cardiac event. The monitor records a short-duration electrocardiogram and can store up to six such events. The patient can send the recording to a receiving center via a telephone modem (Thakor et al., 1984). The receiving station records the arrhythmia and forwards a report to the attending cardiologist. The patient might carry the monitor for a month or more.

Diagnostic Radiography

Conventional radiography has been employed in the diagnosis of cardiovascular disease in the form of the basic chest X-ray. Of interest to the cardiologist would be enlarged heart size, fluid between the membrane lining the heart and the heart itself, and fluid in the lungs.

CT scanning was not previously available to evaluate heart disease because the organ of interest—the heart—was in constant motion (Cunningham and Judy, 1995). Fast CT scanning has overcome this problem by employing basic CT scanning technology and enhanced computer technology that can reconstruct a beating heart (Boyd and Lipton, 1983; Ritman, 1990).

While not a radiography technique, positron emission tomography (PET) scanning is also employed to evaluate heart disease. PET involves the tracking of a nuclear source injected into the patient (Budinger and VanBroeklin, 1995). ET scanning is not a stress test like that used in nuclear medicine. Limitations in PET technology are the expense of the hardware, the necessary radiation protection for the facility, and the availability of nuclear pharmacology.

Diagnostic Ultrasound

Also known as cardiac ultrasound, diagnostic ultrasound is used to diagnose, in real time, the movement of valves and the walls of the heart during a cardiac cycle. Valvular stenosis and regurgitation, septal defects between the chambers, ventricular dyskinesia, and growth of myxoma (a type of cancer) can be diagnosed (Yoganathan et al., 1995; Ferrara, 1995). An echocardiogram is a method of studying the heart's ventricular size, function, wall thickness, motion, and valves by using Doppler ultrasound.

Ultrasound is becoming the standard assessment tool for cardiovascular disease. It is completely noninvasive, requires no exercise risk, uses no contrast media, and uses no ionizing radiation. The technology has evolved from simple M-Mode (motion mode) ultrasound, to 2-dimensional ultrasound and color ultrasound (Ferrara, 1995).

As with other diagnostic techniques, the ultrasound is both science and art. The science of what ultrasound can show has been well established. The art is in the ability of the cardiologist to interpret what he sees.

Diagnostic Cardiac Catheterization Laboratory-Based Technologies (Invasive)

The cardiac catheterization laboratory has evolved into a highly sophisticated diagnostic laboratory. Typical technology employed includes an imaging system, physiological monitoring, and radiographic recording technologies for both standard radiographic images and cinematic film, and an injector for radiopaque dye. By its nature, all procedures performed in the cardiac cath lab are invasive.

Coronary Angiogram

The standard procedure performed in the cardiac cath lab is coronary angiography (Van Lysel, 1995). This procedure involves the introduction of a catheter into the right or the left side of the heart to study the pressures in the central vein, across the valves of the arteries and the chambers of the heart. The volumes in the cardiac chamber during the cardiac cycle and the patency of the coronary artery are also measured by observing the flow pattern of radiographic dye injected through the catheter.

Right-heart catheterization measures the right atrial, right ventricular, pulmonary artery, and pulmonary capillary wedge pressures, oxygen saturation, and cardiac output. The catheter is inserted through the femoral vein or subclavian vein. Left-heart catheterization measures the aortic and mitral valve stenosis and regurgitations, global and regional left-ventricular functions, and coronary arteriography. The catheter is inserted through the femoral artery or the brachial artery.

The radiographic system typically employed in the cath lab is a c-arm single plane or bi-plane fluoroscopy system. The c-arm arrangement allows for easy viewing of right-heart or left-heart features. Bi-plane imagery also facilitates the examination of left-heart or right-heart features without the need to reposition the patient. The X-ray table is typically a cradle arrangement that allows the patient to be moved during fluoroscopy. The dye injector can be synchronized with the radiographic unit in order to capture the dye-flow pattern. During the procedure, both conventional radiographic film and cine film of the dye distribution are made.

Physiological monitoring includes surface electrocardiograph recordings as well as intra-cardiac electrocardiograph recording. Because of the very low electrical signals being recorded, electrical background noise must be suppressed. The electrical grounding system in the cath lab is a critical installation issue. The physiological monitor will also typically record multiple intra-cardiac invasive blood pressures.

A variation of the cardiac cath lab is the vascular lab. There, the intent is to examine the vessels other than those associated directly with the heart. The vascular lab would

employ similar radiographic equipment in order to evaluate the vessels serving, for example, the brain.

Electrophysiology Study

A separate area of diagnosis performed in the cardiac cath lab is an electrophysiology study. There, the cardiologist seeks to identify aberrant electrical pathways that can cause cardiac arrhythmias. The technology employed includes the standard cath lab radiographic and physiological monitoring equipment. In addition, equipment specifically designed to study or "map" cardiac electrical impulses is employed.

The cardiologists will electrically stimulate the heart and will record the electrical conduction timing from the origination node in the heart, the sinoatrial node, through the electrical pathways in the heart, the HIS Bundle, and finally through the distribution system to the heart muscle itself. These latter conduction structures are the Purkinje fibers. A three-dimensional map of cardiac electrical activity can be developed. Once the pathways have been identified, a radio frequency pulse is delivered to cut the aberrant pathway. The pulse is very similar to that developed in electrosurgery devices. The procedure is called a "radiofrequency ablation." The procedure is both diagnostic and therapeutic in that a cure to the arrhythmia results from the ablation.

As with any cardiac electrical measurements performed in the cath lab, electrical background noise can disrupt the procedure. Electrical grounding, to include isolation transformers on critical diagnostic equipment, is required.

Intra-Cardiac Catheters

The catheters employed in cardiac diagnosis are a technology all their own. There, multi-lumen catheters are employed to measure pressures, inject dye or medications, and measure electrical activity. Measuring electrical activity requires that the catheters incorporate multiple poles spaced along the distal tip of the catheter. The catheter must be large enough to accommodate the lumen and electrodes, yet small enough and flexible enough to be inserted in the heart via a femoral or jugular vein.

A different type of catheter is used for the electrophysiology study. This catheter will incorporate multiple electrodes to measure the intracardiac electrocardiogram, as well as a pole for the delivery of the radiofrequency pulse to ablate the electrical pathway.

Surgical Interventions for Cardiovascular Disease

Operating Room–Based Surgical Interventions

Surgical interventions for cardiovascular disease include, at one extreme, cardiac transplantation, and at the other, replacement of diseased valves and other heart structures. Because the heart is essentially a pump, surgical interventions have been compared to "plumbing repairs". For some congenital heart defects, the surgeon does, in fact, reroute the great vessels serving the heart. Patches can be placed on or in the heart to correct holes or areas where heart muscle has died. Figure 94-2 shows a typical radiology department special procedures room where interventional cardiovascular procedures are undertaken.

The intervention can be limited to the chest cavity or can be an open-heart procedure. For the latter, the technology employed includes advanced physiological monitoring, anesthesia support equipment, and the heart-bypass (extracorporeal) pump (Dorson and Loria, 1988). Because the "pump" supports both circulation and respiration, the blood circulating through the pump may be warmed or cooled. In addition, in order to limit blood loss, a blood scavenger system, or "cell saver," (Haemonetics Ltd.) may be employed. Such a device separates and washes red cells from blood aspirated at the operative site. The washed red cells then may be resuspended in plasma protein solution and autotransfused.

Perhaps the most common cardiac surgical procedure is the coronary artery bypass graft (CABG or "cabbage"). There, the coronary arteries serving the heart are bypassed with a vessel taken from the patient. One or more coronary arteries may be bypassed in this manner. This is one of the most common surgical procedures performed in the United States.

Figure 94-2 Special procedures room.

The cardiovascular surgeon also performs vascular procedures. One common procedure is a carotid endarterectomy. In this procedure, the surgeon physically removes plaque from the inside lining of the carotid artery, restoring normal blood flow to the brain.

A number of technologies are used in support of cardiac surgery. Physiological monitoring after cardiovascular surgery may include cardiac output monitoring. Several techniques have been employed (Geddes, 1995). The current state of the art in cardiac output measurement is "thermal dilution." The "gold standard" of any cardiac output testing is the Fick Method. In conjunction with cardiac output monitoring, pulmonary arterial pressure (Gardner, 1988) can be continuously measured using a Swan-Ganz catheter (Swan et al., 1970).

Heart muscle that has been damaged as a result of blocked coronary arteries might need supplemental pumping support postoperatively. Intra-aortic balloon counterpulsation (balloon pumping) is typically used. Intra-aortic balloon pumps (Jaron and Moore, 1988) utilize a balloon placed in the descending aorta. Pulsating counter to the pumping of the heart, the pump reduces the workload on the heart by reducing the peripheral vascular pressure. The pump then provides support pumping to maintain adequate blood pressure for circulation (see Figure 94-3).

Another form of counterpulsation is enhanced external counterpulsation. This noninvasive treatment is designed to lessen the work for the heart, usually for patients with angina (Lawson et al., 2000). Blood pressure cuffs are placed on the legs, and in a coordinated way some cuffs are inflated with air while others are deflated. It helps the blood circulation in the heart. Treatments are observed in a doctor's office, lasting one to two hours each, and then are repeated over time. Figure 94-4 shows an ambulatory care patient receiving enhanced extracorporeal counterpulsation treatment.

Cardiac Catheterization Laboratory–Based Surgical Procedures

It is probably incorrect to classify the following procedures as surgical procedures. However, they are discussed under this heading because they often replace procedures performed in the operating room.

The interventional cardiologist has had a significant impact in moving cardiovascular surgical procedures out of the operating room and into the outpatient setting of the cath lab. The majority of the interventions have been directed at clearing blockages in the coronary arteries, providing a less costly, safer alternative to CABG.

The techniques and technologies used for clearing the coronary arteries include coronary angioplasty (also known as "percutaneous transluminal coronary angioplasty," or PTCA), stenting, and lasers. The technology and techniques have changed over the past 10 years and continue to be an intense area of clinical research. The basic technology employed in the cath lab is the same as that used for a coronary angiogram, but the change has been in the type of catheter used and in the skills of the interventional cardiologists.

In coronary, or balloon, angioplasty, a catheter is threaded into a blocked coronary artery (Walton, 2002). A balloon on the tip of the catheter is then inflated. The inflation of the balloon pushes the plaque on the inside of the artery wall back, reopening the artery. Stenting is a modification of this procedure. There, once the plaque is pushed back, a stent or rigid tube is positioned inside the artery to keep plaque from reclosing the artery.

In both procedures, reocclusion of the artery can occur. Repeat procedures can be performed, although there is a risk of rupture of the coronary artery, or releasing plaque into the circulatory system. Various technologies are under investigation to work in conjunction with balloon angioplasty and stenting to reduce reocclusion.

Other Technologies in Cardiovascular Disease

Three other technologies are used for the treatment of cardiovascular disease: Pacing, defibrillators, and drugs.

Figure 94-3 Intra-aortic balloon pump being prepared by a clinical engineer.

Figure 94-4 Vasogenics enhanced extracorporeal counter-pulsation system treating an ambulatory patient who is being treated on an out-patient basis. Those observing the procedure are clinical engineering interns.

Pacemakers

Pacemaker technology has evolved in both sophistication and reduction in physical size (Geddes, 1995). In addition, improvements in battery technology, such as the lithium battery, now provide pacemakers with multiyear life spans. Battery life has been improved because of new battery technology and because of better pacemaker lead wires and electronics with lower power consumption. Pacemaker technology, itself, has evolved to include pacemakers where a single unit can stimulate either the atrium or the ventricle.

The traditional pacemaker application is to stimulate the heart when the patient's own rate slows below a preset limit, or to detect certain arrhythmias and to override the arrhythmia. The newest technology (as of the time of writing) in pacemakers is a pacemaker intended to be used for patients in congestive heart failure. There, the pacemaker attempts to stimulate the atrium and ventricle in a pattern that is similar to the heart's natural pattern, a bimodal pacemaker.

The pacemaker is typically implanted during a cath lab procedure (Forde and Ridgely, 1995). Previously, the procedure was performed in the operating room. The pacemaker lead wires are installed in much the same fashion as a catheter insertion for a coronary angiogram. The pacemaker "generator" is installed in a pocket under the skin. The pocket is created using a local anesthetic.

Defibrillators

Defibrillator technology has changed dramatically since 1995 (Tacker, 1995). Implantable defibrillators are available, using the same technology and implantation techniques used for pacemakers (Duffin, 1995). They are highly effective and reliable.

External defibrillators are undergoing a metamorphosis of sorts. What has been the tradition in defibrillators (a single, pulse-modified Lown waveform) is being replaced with a biphasic, modified Lown waveform. As a result, the standards for defibrillation are changing, with lower maximum output required to achieve defibrillation. There remains controversy over the effectiveness of the biphasic waveform, yet many equipment manufacturers have changed their product lines to feature only biphasic units.

Drugs

Technology in health care comprises three components: Medical devices, techniques, and pharmaceuticals. In medicine, drugs are effective technologies for the treatment of cardiovascular disease. Drugs that are used to reduce blood pressure, increase blood pressure, increase cardiac muscle contractility, and reduce cholesterol levels are valuable adjuncts to the medical devices and techniques discussed above. While a description of drugs and their applications is beyond the scope of this chapter, the reader should be aware that pharmaceutical interventions in cardiovascular disease are an essential part of the total technology picture.

General Hospital Devices: Beds, Stretchers, and Wheelchairs

Joseph F. Dyro

President, Biomedical Resource Group
Setauket, NY

Wheelchairs, beds, and stretchers are found in abundance in hospitals, short- and long-term care facilities, and the home. These devices are not high technology devices in general and are usually classified as low-risk devices. As a consequence, these devices often received much less attention than high-tech and high-risk devices such as defibrillators, electrosurgical units, anesthesia machines, and dialysis units. Nevertheless, they present a finite risk to patients and must not be ignored. Beds, stretchers, and wheelchairs have caused serious injury and death. This chapter addresses these devices and others usually referred to as “general hospital devices” and “rehabilitation devices,” such as patient lifts, parallel bars, and chairs. Recommendations are made in the areas of evaluation, purchasing, training, service, modification, and obsolescence. Guidelines are presented for investigation of incidents and accidents involving these devices. Several case studies are presented to illustrate the types of risks involved and steps to take to minimize or eliminate these risks to patients and staff.

Beds

The bed is often forgotten because clinical engineering departments focus attention on more complex devices such as defibrillators and patient monitors (Poulsen, 2001). Unfortunately, such inattention can result in poorly maintained and hazardous beds. Bed, stretcher, and wheelchair management has been successfully incorporated into a clinical engineering department (Dyro, 1993). Clinical engineers have participated in the evaluation and selection of appropriate technologies. Appropriately trained general mechanics have proven themselves able to work effectively under the supervision of clinical engineers to inspect and maintain these devices.

Patients in the hospital or home care spend most of their time in bed. As technology has advanced, the first beds found in some of the first hospitals (Figure 95-1) have gotten more complex and multifunctional. The bed is a medical device and is found in many configurations; e.g., electric beds and non-electric (i.e., mechanical) beds. The hospital bed today may be hydraulically or electrically powered, enabling the user to position the bed at various levels above the floor, and various parts of the mattress surface to adjust the position of the head, knee, and foot positions. Accessories for beds include head and foot boards, bumpers, mattresses, mattress covers, occupancy alarms, bed-wetting alarms, pads, railing pads, bedrails, trapezes, and scales. Side rails come in a range of styles including removable side rails, adjustable side rails, and half-side rails.

Special beds include flotation-therapy beds to reduce the risk of decubitus ulcer formation, barobeds to support extremely obese patients (Figure 95-2), and circle beds to position and stretch patients. Advanced life-saving and life-extending interventions find more patients staying in bed longer, thus increasing the likelihood of the development of skin ulcers from prolonged contact of the patient with the bed under pressure. Obesity is ever increasing in our society. As more extremely heavy patients are cared for or are treated for their obesity with, for example, bowel resection, medical devices are feeling the strain (BS&S, 2002). Circle electric beds and other devices (e.g., traction tables) that relieve the stress imposed on the skeletal system by gravity are seeing increased use as back problems afflict an increasingly sedentary society. A wide variety of beds accommodate the many special needs of the broad spectrum of patients. Beds include the following types: Air fluidized beds, birthing beds, circle electric beds, cribs, electric beds, obese electric beds, flotation-therapy beds, fluoroscopic beds, hydraulic beds, infant incubators, infant radiant warmers, rocking cradles, rocking beds, bassinets, pediatric beds, labor beds, low-air-loss beds, mechanical beds, metabolic beds, orthopedic beds, and tilt beds.

The numerous considerations taken into account when specifying a bed include patient age, size, weight, and condition. Criteria also include the intended use and the environment in which it will be used. Beds must accommodate a wide range of physical characteristics of the patient, from a small, pediatric patient to an obese adult. Included in this chapter are the bed features of devices including infant incubators, radiant warmers, bassinets, and cribs. These devices are included because in many hospitals they are treated to the same lack of attention given to a hospital bed. In several of the incidents that the author has investigated, lack of medical device management was the root cause of patient injury and death (see Chapter 64).

Figure 95-3 shows a newborn infant (this author’s daughter) resting comfortably on a mattress in an infant incubator. At the other end of the life cycle curve, a centenarian, (the

newborn’s great aunt) rests comfortably in an electric bed in a home care situation (Figure 95-4). Note that many design characteristics of an adult bed are found even in an incubator. For example, the infant is resting on a mattress; the mattress can be inclined; the mattress is appropriately sized so as not to permit gaps and spaces that could entrap limbs; and the infant is restrained from leaving the bed surface and falling to the floor by the incubator enclosure that consists of rigid walls and movable access panels (i.e., side panels). The concerns to ensure patient safety, whether for the infant or the adult, revolve around issues such as patient entrapment, patient containment, patient comfort and support, patient positioning.

Design Features

Figure 95-5 is an illustration of a typical hospital bed, showing several design features. The following are the principal design features of beds:

Frame	Casters and wheels	Brakes
Side rails and latches	Foot and head boards	Electronic controls
Mattresses	Padding and bumpers	Motors
Gears	Positioning mechanisms*	IV pole connectors

*Trendelenburg, reverse-Trendelenburg, Fowler, foot, head, and knee elevation

Bed Management

Clinical engineers should actively participate in the assessment, evaluation, purchasing, maintenance, repair, modification, and obsolescence of beds and bed accessories. Neglecting these medical devices increases the risk of patient injury from a variety of mechanisms, several of which are described below.

Injuries

Several examples follow, illustrating that death or serious injury can occur from the use of adult beds and infant incubators.

Entrapment

Bedrails intended to keep a patient in bed and to prevent the patient from falling out of bed have entrapped patients, causing death and serious injury. This happens when a disoriented patient attempts to leave the bed and becomes entangled in the bedrail or between the bedrail and the bed or does not attempt to leave the bed but simply slips between the mattress and the bedrail (Miles, 2002). About 2.5 million hospital and nursing-home beds are in use in the United States. Between 1985 and 1999, 371 incidents of patients caught, trapped, entangled, or strangled in beds with rails were reported to the United States Food and Drug Administration. Most patients were frail, elderly, or confused (FDA, 2000). Parker and Miles (1997) described 74 entrapment deaths that occurred between 1993 and 1996 and described the mechanisms of these deaths. Miles and Parker (1998) show pictures describing two cases of fatal bedrail entrapment. Figure 95-6 shows several points at which a patient can be entrapped in a bed (FDA, 1995). The incidence of fatal bedrail entrapments have lead some to question their use or to conclude that bedrails should not be used in ambulatory patients (Huffman, 1998; Hanger et al., 1999).

Figure 95-7 is a re-enactment of the scenario described at hazard point 3 in Figure 95-6—a strangulation of a patient who attempted to get out of bed only to become hung up on the side rail. (The volunteer for the re-enactment suffered no injuries.)

The lifetimes of the various components of a bed differ. For beds, it is 25 years; for rails, 10–15 years, and for mattresses, about 5 years (Miles and Levenson, 2002). In this mix-and-match situation, the rail-to-bedframe spacings can vary over the life of a bed. Furthermore, adjustments to the bed are typically made by housekeeping, janitors, or maintenance workers—personnel who have little familiarity with medical devices and the serious consequences of improper bed configuration.

After many years of silence and neglect, the health care community is taking some action to address the problem (Parker, 1997). In 1999, the Hospital Bed Safety Working

Figure 95-3 Infant incubator bed for a neonate.

Group (HBSW) was established at the Department of Health and Human Services in Washington, DC under the leadership of the United States Food and Drug Administration (FDA). Joining the FDA in this effort are representatives from the medical bed industry, national health care organizations, patient advocacy groups, and other federal agencies (Centers for Medicare & Medicaid Services; the Consumer Product Safety Commission, and the Department of Veterans Affairs). The Group’s goal is to reduce the risk of entrapment and injuries relating to hospital beds and bedrails through standardization of definitions; standardization of the evaluation of beds, mattresses and side rails; and outreach to providers and patients. Assessment kits supplied by the HBSW enable hospitals to assess the risk levels presented by their beds (BS&S, 2002a). For further information on the activities of the group, see <http://www.fda.gov/cdrh/beds/index.html>. Other organizations such as the Joint Commission on Accreditation of Healthcare Organizations (JCAHO)(JCAHO, 2002, 2003) have issued alerts to the health care community regarding the hazard of bed rail entrapment. Recalls have been issued because of possible patient entrapment (BS&S, 2003) and latch failures (BS&S, 2003a, 2003b).

The Health Care Financing Administration (HCFA) and the Food and Drug Administration (FDA) differ in their interpretation of restraints especially as it relates to side rail use. The HCFA’s requirements pertaining to the use of restraints in nursing homes are at 42 CFR Section 483.13 (a). HCFA defines “physical restraints” under “Interpretive Guidance” in the *State Operations Manual* as: “any manual method or physical or mechanical device, material, or equipment attached or adjacent to the individual’s body that the individual cannot remove easily which restricts freedom of movement or normal access to one’s body.”

The FDA defines “protective restraint” at CFR Section 880.6760 as:

“a device, including, but not limited to, a wristlet, anklet, vest, mitt, straightjacket, body/limb holder, or other type of strap that is intended for medical purposes and that limits the patient’s movements to the extent necessary for treatment, examination, or protection of the patient or others.”

The HCFA and FDA recently clarified the distinctions that each agency makes with regard to the definition of restraints (HCFA/CDRH, 2000).

Another form of entrapment occurs when a bed is lowered onto patients or visitors who are under the bed. Adults and children who have crawled under beds have been crushed when beds have been lowered, most frequently when beds have incorporated a “walk-away down” feature that enables the bed to be lowered with the activation of a single control switch.

Figure 95-5 InterRoyal Fred Bed showing typical design features.

Figure 95-6 The four locations on a bed with bedrails, where patients have most frequently become entangled: (1) head inserted between widely spaced vertical bars in the bedrails; (2) patient slid either on their abdomen or on their back through the slot between head and foot rails; (3) patient slid legs first through the slot until the anterior neck jammed against the rail; and (4) head buried in the triangular space created by the right angle of the bedrail and the headboard with the mattress-corner curves (FDA, 1995). Parker (1997) describes death from asphyxiation when a patient's entire body becomes entrapped in the space between the side of the mattress and the bedrails and when the head of the patient in bed passes over the top of the bedrail and the throat rests on the rail.

Falls

Falling is a common cause of morbidity and the leading cause of nonfatal injuries and trauma-related hospitalizations in the United States (Baker et al., 1992). Falls while getting into and out of beds are too common. Ironically, risk of falling may be increased by the presence of bedrails because some people try to climb over them and fall in the process (Parker, 1997). Improper bed and bed rail height are factors contributing to falls associated with beds (Agostini et al., 2001). Inadequately latched bed rails or deteriorated latches that allow side rails to collapse with no or some assistance from the occupant, or rails that are ineffective in restraining patients may contribute to patient falls (Miles and Levenson, 2002). The button type of latch is particularly subject to deterioration. A spring-loaded button is constrained to a hole in a side rail vertical tube member. To raise or lower the side rail, the button must be pushed in to allow free movement of the tube member. Over time, the button slides up and down, and the tubes that are sliding over the button wear away the button, rendering the button-latch ineffective (Health Canada, 1988).

The author has investigated incidents in which infants have fallen out of incubators by crawling out of open or inadequately closed or locked hand ports, and when they have fallen out of radiant warmer bassinets when side walls have collapsed because of inadequate and defective latches. (Figure 95-8.) The striker plate shown in Figure 95-8 was manufactured from a soft metal that, over time, wore away as shown, rendering the latch ineffective for securing the door.

Figure 95-7 Reconstruction of a bedrail entrapment event.

Impalement

While relatively rare, cases of impalement on bed parts have occurred (Parker and Miles, 1997). The author investigated an impalement event in which a nursing home resident had fallen from her bed (Figure 95-9), impaling her throat on the vertical element of the half-bed side rail lying on the floor as shown in Figure 95-10.

Burns

Serious burns have occurred when neonates in incubators crawled from the mattress surface to hot air vents. Lack of maintenance and inspection allowed an infant incubator, missing a barrier separating the infant mattress from the hot air vent, to be used (Figure 95-11). A serious burn resulted when the infant crawled over the hot air vent.

Other Hazards

Electric shock (BS&S, 2003c), fire (BS&S, 2003d), contamination with infectious agents, instabilities (BS&S, 2003e, 2003f), and tipover (MDR, 1988; BS&S, 2003g) are several other hazards that are present in some beds. Power cords of electric beds often have been damaged by being pinched between the bed and the floor, wall, or room furniture. An electrical shock hazard can result from a damaged line cord with missing insulation that is in contact with the bed. Damaged power cords from other medical devices and household appliances such as radios and televisions that are in contact with

Figure 95-8 Incubator door latch striker plate showing wear to soft metal of plate. Such wear enabled an infant to open the door merely by the leaning on the door. Reproduced with permission from Shepherd (2003).

a bedrail also pose a hazard (Figure 95-12). Beds can harbor infectious agents and must be kept clean.

Operating Room Tables

Among the wide variety of tables utilized in health care are the following types: Anesthetist's, autopsy, bedside, blood donor, dissecting, examination/treatment, instrument, nuclear medicine, obstetrical, operating, orthopedic, overbed, physical therapy, proctologic, radiographic, radiotherapy, special procedures, tilt, traction, and urological. They range considerably in complexity and cost. Among the more complex of these are operating room (OR) tables, which are used to support a patient while a surgical procedure is performed (Figure 95-13). OR tables are also referred to as "surgical beds" or "operating room beds."

Design Features

The medical device that is utilized to support a patient undergoing a surgical procedure is known by many names (e.g., surgical table, operating room table, OR table, and surgical bed). Holding steady at the desired height and angles of the patient platform is the most important evaluation criterion of an operating table. As with all medical devices, clinical engineering can contribute substantially in the assessment, evaluation, purchasing, maintenance, repair, modification, and eventual disposition of these devices. OR tables are becoming increasingly sophisticated and complex with microprocessor circuitry and voice-activated table-position control. It is not for this reason alone, however, that CE departments should include service of these devices in their programs. Even the least complicated table, if nonfunctional, severely affects the utilization of an operating room. Cancellation or rescheduling of a surgical procedure equates to a loss of revenue, inconvenience to staff, and a danger to the patient in need of surgery. While infrequent, reports of OR table failure indicate that they do occur, such as the recent report of the top of an OR table becoming detached in the middle of a surgical procedure (BBC News, February 27, 2003).

OR tables are used for a wide variety of surgical procedures, including the following: General, ambulatory, neurological, gynecological, urological, ophthalmological, orthopedic (articulated posturing of patient for reconstructive and reparative orthopedic procedures), minimally invasive (such as endoluminal stent-grafting, abdominal aortic aneurysms (AAA), intraoperative angioplasty, cardio/endo vascular, coronary angiography, mid CAB, mini CABG).

The following is a listing of the four main design features of an OR table and evaluation criteria:

- Table top
- Support base
- Controls
- Power supply

All four design features must result in a stable patient platform that is ergonomically suitable for the operating room staff and that can be attained conveniently, quickly, reproducibly, and reliably. Radiographic imaging during surgery places special requirements on such characteristics of the table top as ease of positioning an imaging devices such as a C-arm and radiolucency, scattering and absorption of X-ray radiation.

Tabletop design criteria include surface area, overall dimensions, articulations (head, back, legs), standard Trendelenburg, reverse Trendelenburg, and various tilt orientations.

Figure 95-10 Side rail.

Figure 95-12 The line cord of a radio with worn insulation lying against bedrail.

Figure 95-13 Champagne operating room table.

The versatility of an OR table depends upon the availability of accessories or extensions to accommodate positioning requirements and upon such features as modular design that enables easy reconfiguration of the table for different procedures.

Control of the articulations, orientation, and height of the patient surface should be convenient, quiet, and reliable. Manual positioning, powered positioning regulated by pendant controls that can be accessed at various positions around the table, wall-mounted controls, and voice-command controls are considerations. Power-assisted patient-positioning systems should operate smoothly and quietly throughout the full range of height and tilt positions of a table's patient surface. OR tables can be positioned by manual, hydraulic, electric, or electro-hydraulic power sources. A manual backup system must be incorporated for times of electrical failure.

The structural characteristics will dictate the weight-bearing capacity, stability, and maneuverability of the table. Movable tables must be stable on level and irregular surfaces and typically have wheels and casters that provide for good maneuverability and stability. Some tables consist of permanently mounted OR table supports, such as pedestals, which accept modular table surfaces.

OR Table Accessories

A wide variety of accessories are utilized in conjunction with OR tables, including such devices as pads, clamps, tabletop extensions, head rest, stirrups, Clark crutch sockets, arm boards, arm and hand tables, restraints, retractors, leg and calf support, abductor bars, sacral rest, and perineal posts.

Hazards

The most prevalent complication associated with OR tables is that of skin lesions and underlying tissue trauma associated with ischemia induced by prolonged excessive pressure to parts of the circulatory system of the patient.

Pressure Necrosis

Constant pressure applied to parts of the body affects the underlying blood circulation. If perfusion of a volume of tissue is compromised for a long enough period, ischemia results and can lead to necrosis of the affected tissue. Such accessories as retractors, mattresses, railings, and leg supports, if inappropriately designed, manufactured and utilized, can be that source of excessive pressure that can be injurious to the patient during long operations (Gendron, 1988). For example, the author investigated an incident in which a patient had suffered neurological damage as a result of prolonged, high-pressure contact of a limb with the vertical elements of the Pittman retractors, as shown in Figure 95-14. Surgical staff must be appropriately trained to avoid such situations and to use adequate padding to distribute the force of a hard object over a large area in order to minimize the pressure upon the patient's vasculature.

Chemical Burns

Mattresses have been the cause of serious skin damage to patients undergoing long procedures. Skin lesions can be caused by such mechanisms as excessive temperature,

Figure 95-14 Pittman retractors.

pressure necrosis, chemical attack, electrical current, and laceration. The author unraveled a mysterious, full-backside skin lesion that a patient suffered while undergoing a six-hour cardiovascular procedure. Typical sources of insult such as hyperthermia, mattresses, and electrosurgical generators were first considered. It was only when the staff during interview admitted that the OR table mattress had recently been sterilized by ethylene oxide (EtO) and that, because of the OR scheduling demands, was returned to service immediately upon completion of the sterilization, that the author realized that the lesion was caused by EtO that had remained in the mattress after sterilization. The central sterile supply and OR staff had not taken adequate precautions to ensure that the mattress had been sufficiently aerated after EtO sterilization to allow the elution of the caustic sterilant.

Instability

Unstable supports for the limbs have resulted in product recalls (BS&S, 2003h) and interruption and delay in surgical procedures (BBC, 2003).

Stretchers

A stretcher, also referred to as a “gurney” or a “patient trolley,” is a medical device upon which a patient lies for transportation. A wide variety of stretchers are available and their design depends upon the use to which the stretcher is put. A stretcher may be as simple as those utilized in military conflicts or emergency rescue—essentially, a piece of canvas affixed to two sturdy poles on which the injured person is carried by rescuers. Stretchers for use in the field can be considerably more complicated, with more features such as the ambulance stretcher shown in Figure 95-15, designed so that its undercarriage will fold, thus allowing the stretcher to be slid into the ambulance compartment.

Figure 95-15 Ferno-Washington collapsible stretcher being taken from an ambulance.

This stretcher also has wheels to facilitate transport over smooth terrain. Hospital-based stretchers are used to transport patients between patient rooms, and from a room to diagnostic and therapeutic departments such as X-ray and the operating room. Figures 95-17 and 95-18 show two devices designed for transporting patients to and from the operating room and post-anesthesia recovery area. These hospital-based stretchers range from the simple to the complex, incorporating such features as shelves for physiological monitors and hydraulically powered mechanisms for adjustment of stretcher height and mattress position.

Design Features

In selecting a stretcher, one should evaluate it for the presence of pinch points, entrapment zones, ease of maneuverability, adequacy of locks and brakes, ease of operation of bed-positioning controls, clarity of labeling and indicators (e.g., for height adjustment), weight capacity, surface area, ease of cleaning, and sturdiness of construction. Stretchers are subject to considerable shock and vibration, as they are intended to move about and often inadvertently collide with walls, door jambs, other stretchers, beds, and furniture.

Listed below are a number of design features that should be included in any pre purchase evaluation of stretchers. These features, similarly, should be carefully examined in the course of routine maintenance.

Mattress	Frame	Side rails
Head and foot boards	Wheels and casters	Brakes
Steering guides	Hand holds	Padding
Bumpers	Shelves and storage areas	IV poles
Oxygen cylinder storage	Positioning systems	Labels and indicators

Stretcher Incidents

Defective design, manufacture (e.g., defective welds (BS&S, 2003i)), maintenance, repair, and improper use of stretchers can result in patient injury.

Figure 95-15 shows a stretcher whose undercarriage can fold up, thus permitting positioning in an emergency vehicle. Defects in latching mechanisms and improper use can result in the unexpected collapse of the undercarriage while the patient is being transported outside of the ambulance with legs in the fully extended position.

Figure 95-16 shows a Stryker PACE stretcher involved in an incident in which a nurse allegedly pinched her finger between the corner of the stretcher and the wall. Extensive testing by the author confirmed that the stretcher had excellent maneuverability and that all wheels and brakes were in conformance with specifications.

Figure 95-17 shows a Stryker Model 935 SurgiCare clean-corridor system stretcher. A patient allegedly injured fingers while attempting to sit on the stretcher. The author found that inadequate maintenance and failure to properly install the manufacturer’s product modification allowed a pinch point to exist.

Wheelchairs

Wheelchairs have aided the movement of people for centuries. The ancient wheelchair depicted in Figure 95-18 stands in stark contrast to wheelchairs incorporating the most recent technological developments, such as the one shown in Figure 95-19. Patients whose ambulation is impaired are frequently transported about the hospital in wheelchairs. Wheelchairs are found increasingly in nearly every setting as architectural barriers to access are removed in response to federal legislation ensuring equal access to the handicapped. Patients, their relatives, and their caregivers have ample opportunity to see and feel them. Often, the first medical device to which a patient is exposed is a wheelchair. A patient seated in a wheelchair that is dirty, in disrepair, or malfunctioning forms a poor impression of the hospital, which is responsible for the wheelchair’s maintenance. That same patient is exposed to increased risk of injury from a poorly maintained wheelchair (Young, 1985). If a simple wheelchair cannot be adequately maintained, what does that say about the safety and performance of more sophisticated devices to which a patient might be exposed? Improper use and poor maintenance and repair contribute to wheelchair hazards (HPCS, 1994). According to one study (Calder and Kirby, 1990), fatalities occur in approximately 0.2% of serious wheelchair-related accidents, or 7.6 fatal accidents per 100,000 users per year. Most of these fatalities were associated with falls and tipping. Active research programs (Kirby et al., 1989a, b), advances in wheelchair design, and adoption of international safety and performance standards will mitigate some of these problems (Brubaker, 1988), but the need for vigilance, proper utilization, and adequate maintenance will continue to exist. For a detailed discussion of wheeled mobility, wheelchairs, and personal transportation, the reader should consult the work of Cooper (1995).

Wheelchair Design Features

Wheelchairs, both motorized and nonmotorized, share many design features. The significant design features of a wheelchair are listed below:

Frame	Wheels and tires	Casters
Brakes	Handles	Arm, leg, and foot rests
Trays and tables	Storage compartments	Seats
Padding	Anti-tip devices	Motors and gears
Drive mechanisms	Batteries and chargers	Electronic controls

Figure 95-20 shows a schematic representative of a typical nonmotorized wheelchair and terminology used to describe salient features of the wheelchair.

Figure 95-16 Stryker PACE bed.

Figure 95-17 Stryker SurgiCare model 935.

Wheelchair Management

Management of wheelchairs entails the elements of assessment, evaluation, purchasing, maintenance, repair, modification, and obsolescence. The numerous considerations taken into account when specifying a wheelchair include patient age, size, weight, and condition. Criteria also include the intended use and the environment in which it will be used (Brubaker, 1986). Wheelchairs must accommodate a wide range of physical characteristics of the patient from a small pediatric patient to an obese adult. Wheelchairs are used for transfer from a patient bed to an examination room, from the discharge desk to the awaiting car, van, or ambulance, from the emergency room to the treatment area and as an alternative to lying in bed. Wheelchairs are used increasingly by athletes in track and field, basketball, and other sports (Brubaker, 1988). Patient conditions dictate the amount of assistance needed in transferring a patient to and from a wheelchair and for movement.

A wide variety of accessories are available for wheelchairs, including trays, seats, and rests for arms and feet. Motorized and nonmotorized wheelchairs (Figures 95-21 and 95-22) are manufactured by scores of companies and used by millions of people throughout the world.

Safety Considerations

Understanding the hazards associated with wheelchairs is beneficial for the manufacturer who must design these devices to eliminate such hazards. A retrospective based upon the literature, the author's accident investigations, and hazard-reporting systems has revealed a number of injuries resulting from wheelchair use. The following describes and lists the most prevalent dangers.

Tipping

Tipping to the sides or forward or backward can cause a wheelchair to tip over. The occupant of such a wheelchair at the time of tipover can be seriously injured as he strikes the floor. Irregular surfaces, rough terrain, inclines, gaps on the surface, or a combination of the former can cause a wheelchair to tilt far enough to tip over. A wheel falling off would also cause the wheelchair to tip over.

Collapse

If the wheelchair frame loses its structural integrity through a broken frame (e.g., defective welds or metal fatigue) or loose or missing fasteners (e.g., screws, nuts, bolts), the wheelchair may no longer be able to support the weight of, and forces exerted by, the patient. The author has investigated incidents in which wheelchairs have collapsed from inadequate and improper repair and maintenance.

Brake Failure

Brakes to prevent the wheels from turning might not adequately engage, thus permitting the wheelchair to move as the patient is transferring. Falls can result. Wheelchairs on inclines may run away, gain momentum, and forcibly eject the patient when the wheelchair comes to a sudden stop. Brake mechanisms, such as the one shown in Figure 95-23, require inspection and maintenance to ensure that fasteners are secure and properly adjusted. Testing the adequacy of breaking force should be done after servicing.

Figure 95-21 Nonmotorized wheelchair.

Figure 95-22 Motorized wheelchair.

Figure 95-24 Missing a protective cap, the sharp edge of a wheelchair frame lacerated the skin of patient during transfer.

Figure 95-23 Brake mechanism of wheelchair.

Pressure Points

Irregular, hard surfaces can result in high-pressure points or areas on the patient's body (e.g., thighs, buttocks, and back). Decubitus ulcer and pressure necrosis can result. Research has resulted in seat-cushion designs that minimize these dangers (Ferguson-Pell et al., 1986).

Sharp Edges and Pinch Points

Patients may have reduced sensitivity to tactile stimulation. Rough surfaces and sharp and jagged edges can cause lacerations of the skin (Figures 95-24 and 96-25).

This is especially possible during transfer and may affect many areas of the body such as the hands, fingers, wrist, arm, and legs. Fingers can be pinched if caught between hard, metallic surfaces (e.g., between frame and foot and leg rest; in the levers that actuate the brake; and between wheel spokes and frame).

Susceptibility to Electromagnetic Interference (EMI)

Numerous cases have been reported of motorized wheelchairs and scooters moving in an uncontrolled fashion when subjected to electromagnetic radiation (Witters and Ruggera, 1994). Serious EMI reactions by these devices over a wide range of radio frequencies (covering many private and commercial transmissions) were observed in CDRH laboratory investigations and testing (Witters, 1995). EMI can occur in the presence of a wide

Figure 95-25 A broken footrest left a sharp edge and a cutting hazard.

spectrum of electromagnetic energy frequencies and intensities. Sources of EMI include pagers, cell phones, aircraft beacons, radio and television transmissions, and common household appliances and tools such as microwaves, electric light dimmers, electric drills, and saws (Dyro, 1995). While the FDA has done extensive testing of the susceptibility of wheelchairs to EMI and has advised the manufacturers of its findings, clinical engineers should remain vigilant to spontaneous activation of powered wheelchairs, especially those that were introduced on the market prior to FDA advisories in 1994 (Albert, 1994; Morrison, 1994). (See Chapters 62, 63, and 103 for more on EMI.) The FDA requires that a warning sticker be placed on each powered wheelchair or scooter, indicating the risk due to EMI (Cooper, 1995).

Figure 95-26 Torn seat cushion allows ingress of filth and vermin.

Fires and Explosions

Gases released by batteries have ignited, resulting in explosion and fire. Wheelchairs recently have been recalled by the FDA because motors could catch on fire (BS&S, 2003j). A short circuit with the charger harness can cause heat damage to the units with potential for fire, according to the FDA.

Lack of Cleanliness

Incontinent patients confined for extended periods of time can soil a wheelchair. The wheelchair that is not properly cleaned at regular intervals becomes a safe harbor for dust, dirt, filth, infectious agents, and vermin. Rust and corrosion can degrade the structural integrity of the wheelchair. Figure 95-26 shows a tear in a wheelchair seat cushion, a point of entry for filth and vermin.

Figure 95-27 Patient vest restraint.

Entrapment

Wheelchairs, stretchers, and beds may be used in conjunction with patient restraints. Restraints can cause death by asphyxiation (Miles and Irvine, 1992; Rubin et al., 1993). The author investigated an incident in which a pediatric patient who had been restrained to a wheelchair with a vests restraint (such as that shown in Figure 95-27) was injured when he attempted to get out of the wheelchair. The wheelchair tipped, and the patient hit his head on the floor.

Other Hazards

Recent recalls of wheelchairs and mobility aids have been made for various reasons, including electrical-grounding defects (BS&S, 2003k), drive wheels coming off axles (BS&S, 2003l), wheels shattering (BS&S, 2003m), and back-support collapse (BS&S, 2003n).

Standards

Voluntary standards for wheelchairs exist (ANSI, 1990a, b, c, and d). Such standards, when adhered to by the manufacturer, assure a minimum level of performance and safety of wheelchairs. While a new wheelchair may have been designed to rigorous standards and may be without defect at the time of incoming inspection, it soon is placed in an often uncontrolled environment, used by uninformed patients and staff, and maintained and repaired by unqualified people. Safety and performance characteristics become degraded, and patient injury results.

Lifts, Parallel Bars, and Chairs

Patient Lifts

Patient lifts are utilized in transferring patients (e.g., from bed to chair). They are relatively simple devices, but they vary significantly in several aspects. For example, heavy-duty lifts accommodate the special needs of extremely obese patients. Figure 95-28 shows such a patient lift. The design features of a patient lift are shown below. When evaluating and purchasing a lift, the clinical engineer should be aware of the following issues: Stability, propensity to tip, ease of movement, swivel bar rotation, sling hook-up strength, load-bearing capacity, strength of welds, caster movement and locking, pinch points, and height of lift range. Accessories such as scales should be examined as well, because they could collapse because of defective design and manufacture (BS&S, 2003o).

| Casters | Latches | Brakes |
| Handles | Swivel bar | Base legs |
| Sling | Sling hook-up | Hydraulic system |
| Manual crank | Battery and charger | Low battery alarm |

Figure 95-28 Invacare Reliant 600 Heavy Duty Power Lifter. This particular lift incorporates a battery-powered, heavy-duty hydraulic lift to meet the special needs of patients who weigh up to 600 lbs.

Figure 95-29 Patient lift.

The following clinical engineering study of patient lifts illustrates that this relatively simple mechanical medical device can fail and seriously injure the patient who is being lifted, and can cause injury to the operator (BS&S, 2003p). A clinical engineering analysis of a hospital incident involving a patient fall from a lift found that lack of or improper maintenance resulted in a failure of a locking mechanism (Grimes, 2003). When using the lift, the patient fell back onto the bed, but the two nurses making the transfer pulled their backs and could not return to work until they recovered.

The lift involved in the incident and shown in Figure 95-29 is designed with legs that can be spread (for increased stability) when lifting patients. Spreading of the lift's legs is accomplished by means of a vertically mounted spreader arm that forces the legs apart through mechanical linkage. A spring and bushing are normally mounted on the arm's pivot shaft. They are designed to force the arm into one of several detents. The lift was found to be missing several components (bolt, steel washers, spacer/spring, spacer/bushing) and that rendered the locking mechanism ineffective (Figure 95-30). A survey of patient lifts on the nursing floors of the hospital where the incident occurred resulting in the discovery of a second unit with missing hardware.

Clinical engineering made the following recommendations for remediation:

1. Repair or replace defective patient lifts.
2. Educate staff on the proper use of patient lifts (i.e., how to stabilize the units when using on a patient). An anecdotal report by a patient-lift user suggests that they might not be properly stabilizing the lift before use; i.e., operators might not be spreading lift legs.
3. Teach staff how to identify and report defective devices.
4. Those responsible for maintenance should schedule visual and mechanical inspections as a part of rounds

Parallel Bars

The following case study illustrates that even what appears to be a rather simple device can prove to be lethal to the patient. A patient suffered a near-fatal electric shock while exercising on motorized parallel bars (Figure 95-31). A patient undergoing therapy in the physical therapy department took his position on parallel bars for stepping exercises. The physical therapist (PT) flicked the toggle switch on the control panel to activate the motor that adjusted the height of the bar. Within seconds, the physical therapist heard a groan and observed the patient grimacing and clutching the stainless steel bar tightly. Noise and sparks were noted coming from the control box. The patient was an unwitting part in an

electrical circuit through which flowed enough electrical energy (i.e., a level above the let-go current (Dalziel and Lee, 1968)) to cause tonic spasms of his musculature. Fast thinking and response by the PT in pushing the patient away from the bar broke the circuit and avoided a death from respiratory collapse.

Investigation by the author revealed that the line cord leading to the motor control box was caught under the base of the parallel bars. As the parallel bar raised, so did the box and the line cord, but because the cord was caught, it could not travel with the box, and a strain was placed upon it at the point of its emergence from the control box. The inadequate strain relief gave way, and the sharp circular cutout in the chassis cut through the insulation of the line cord, enabling the hot conductor to contact the box that was at the same potential as the stainless steel parallel bars. Current flowed through the patient.

Incoming inspection, had it been performed, would have revealed the inadequate strain relief. Clinical engineering inspection of the installation would have revealed the inadequate access to the electrical supply (facility) and the resultant inappropriate device modification for rerouting the AC power cord. Periodic preventive maintenance and inspection would have revealed strain-relief failure from the obvious signs of damaged strain relief, damage to the line cord, and inadequate routing of the line cord as a result of the device modification.

The evening before the incident occurred, a member of the housekeeping department moved the parallel bars during routine cleaning, inadvertently entrapping the line cord (Figure 95-32) and preventing its movement as the bars were raised. The motor control unit rose with the bars, placing strain on the line cord and resulting in the chassis cut-out in the control unit cutting through the line-cord insulation, thus shorting the 120-volt line to the chassis and to the parallel bars.

Chairs

Patient rooms typically are furnished with chairs for the comfort of visitors. Such a simple item as a chair has been shown to have caused adverse reactions from patients and visitors. The author experienced this as he visited a patient in a local hospital. The room was small and cramped, with barely any room to move about. When doctors, nurses, therapists, housekeeping, and other visitors entered the room, one had to move the chair to make space for those entering and moving about the room. This movement of personnel and chairs was ongoing and was not limited to one room. All the rooms to the sides, above, and below this room were similarly appointed. The movement of the chair was a relatively minor inconvenience. The result of the movement was the problem. The feet of the chair scraped against the floor, causing a terrible din that could be heard several rooms away. The patient, seeking rest and recuperation, was not afforded the quiet needed because a horrible screeching of chairs on the floor filled the air all through the day and night.

The installation of an inexpensive, low-friction pad or similar device to the feet of the chairs would have significantly reduced or eliminated the raucous noise. This anecdote emphasizes that one need not expend large amounts of resources to improve the quality of care. Engineering solutions to large problems can be simple and inexpensive.

Management of General Hospital Devices

Management of any health care device technology entails a cradle-to-grave responsibility. Starting with needs assessment, it continues through evaluation, purchase, service, and retirement. The discussion below pertains especially to the clinical engineering management of general hospital devices used in the hospital. Beds, stretchers, and wheelchairs, as well as many other general hospital devices, are used in extended care facilities, nursing homes, and in home care settings and should be managed as well as those found in the hospital (Dyro et al., 1996; Dyro, 1998).

Evaluation and Purchase

Clinical engineering participation in the evaluation of devices prior to their purchase is prudent. To promote the proper selection of a particular wheelchair, for example, the manufacturer may provide detailed selection criteria (Everest & Jennings, 1989a). These criteria, as well as published evaluations, should be consulted when making a device acquisition (HPCS, 1994).

Clinical engineering should provide assistance to the purchasing department to ensure that bid specifications are correct and that necessary terms and documentation requests are incorporated in the bid document. In preparing bid specifications, the clinical engineer should consult applicable standards. For example, numerous standards exist for wheelchairs (ANSI, 1990 a, b, c, and d).

Service

In the case of hospital-based devices, responsibility for obtaining service rests on the shoulders of the facility whether the device is owned by the facility, donated, rented, or on loan. The facility may elect to employ an in-house unit, an independent service organization, the manufacturer, or a rental agency to provide this service. The level of service should be the same, regardless of the choice of support organization. In practice, however, a wide variation in the level of service exists among these organizations.

When general hospital devices are serviced in-house, this service is typically the responsibility of the hospital facilities and maintenance departments, the clinical engineering or biomedical engineering department, or a unit devoted exclusively to these devices only. The author, who has successfully integrated service of these devices into a full-service clinical engineering department (Dyro, 1993), advocates that this responsibility be held by clinical engineering. Where the responsibility falls to facilities or some other hospital unit, it is important to maintain the management principles of inventory control, preventive maintenance, and repair. General hospital devices should not be allowed to fall between the cracks. When these devices are in the home, the home health care agency, rental company, or authorized repair facility is responsible for providing

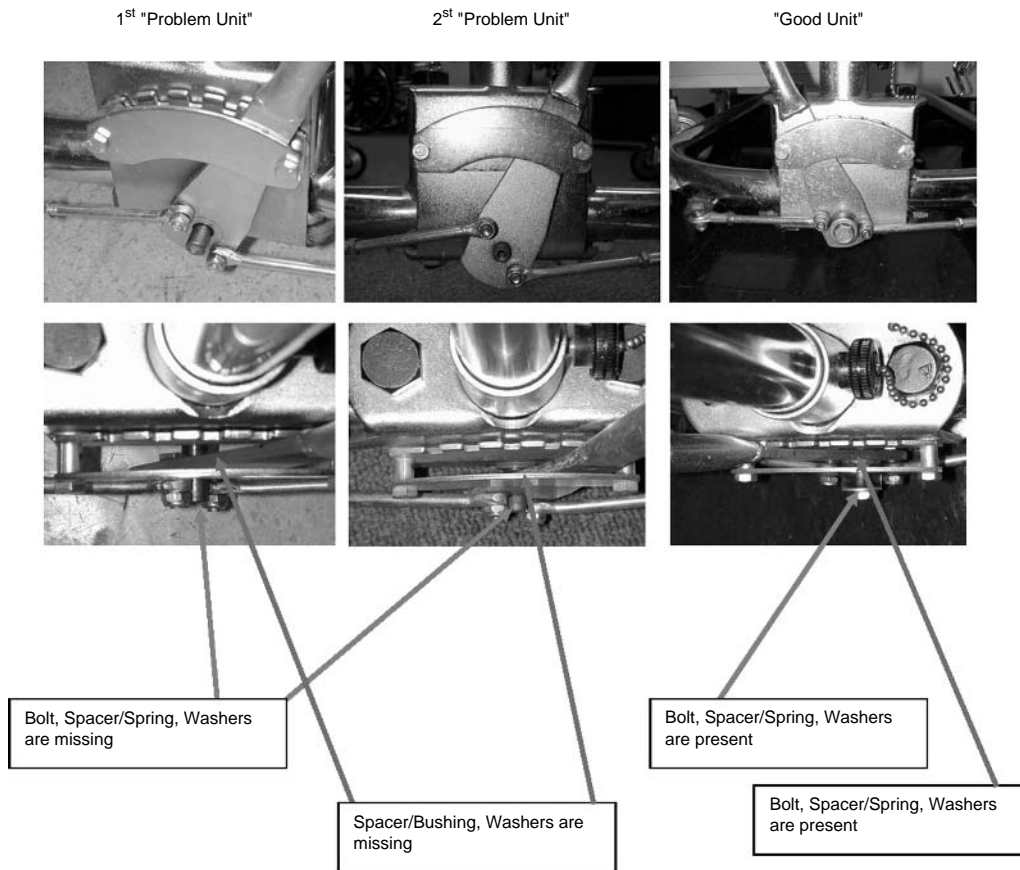

Figure 95-30 Patient-lift locking mechanisms. Mechanisms of three lifts of the same design are shown: 1st problem unit; 2nd problem unit; and good unit.

Figure 95-31 The author in the physical therapy department testing motorized parallel bars.

service. Those responsible for the care of an incapacitated patient are responsible for the coordination of service.

Service of general hospital devices, whether used in the hospital or not, entails the following:

- Incoming inspection
- Preventive maintenance
- Cleaning
- Repair
- Modification

Incoming Inspection

Incoming inspection of all medical devices upon receipt, and prior to initial use, should be performed to ensure that devices are safe and effective for their intended use. The manufacturer (Everest & Jennings, 1989c), professional organizations, the literature, colleagues, and other hospitals can be sources of recommended procedures for this inspection. Table 95-1 is a list of generalized medical device evaluation factors that can serve as a checklist for evaluating medical devices. Knowledge of the evaluation factors will ensure that the evaluation considers all factors affecting safety, performance, and cost. The list is intended to include all facets that are pertinent to evaluations of a broad spectrum of device types. One should include those factors that pertain to the device being evaluated. For example, if the device is a nonelectric wheelchair, then Section 2.4.2 (electrical safety) can be omitted.

The devices should be entered into an inventory management system along with pertinent information such as manufacturer, vendor, date of purchase, purchase price, model number, serial number, and preventive maintenance frequency. Operators and service manuals should be obtained and cataloged at this time. Service staff should receive training in the appropriate service procedures. This may entail attending a manufacturer's training program, an in-house training session, or a self-taught program utilizing the manufacturer's training aids such as books, manuals, and videotapes.

Preventive Maintenance

Preventive maintenance should be performed, and its frequency and intensity should be based upon some objective criteria (Stiefel, 2002). A program based upon the level of risk ascribed to a medical device, taking into account the level of risk associated with the device and the class of patient for which the device is used, is one such example (Gullikson, 2000; Ridgway 2001). Inspection and maintenance procedures for most medical devices are available in the literature and from manufacturers (e.g., Dyro, 1978). (See

Figure 95-32 Device modification at installation leads to potentially fatal electric shock. Simulated line cord is shown in white, leading from the motor-control box down to a channel cut into the wooden base of the parallel bars. The line cord passed under the base and led to a wall-mounted electrical receptacle on the far right.

Figure 95-33 White tape fails to secure side panel.

Chapters 37 and 56 for discussions of maintenance programs and risk management, respectively.)

Cleaning

Cleaning occurs during preventive maintenance and during unscheduled repair service. The patient care staff in the case of hospital-based devices are responsible for daily checks for cleanliness of all medical devices and should either perform simple cleaning or delegate this task to the unit that is responsible for this function (e.g., housekeeping). In the case of devices located in the home, it is the responsibility of the patient or the caregiver to maintain the cleanliness of a device.

Repair

Repair of the device whether in the hospital or the home is performed by qualified service personnel. During preventive maintenance, necessary repairs are made.

Required repairs should not be delayed until the designated time for periodic preventive maintenance but, rather, should be performed as the need arises. To this end, if a device is hospital-based, the hospital staff (including doctors, nurses, technicians and housekeeping—those individuals who have frequent day-to-day contact with these devices) should be aware of the need for repairs and should request that repairs be done. Hospital staff should sequester devices in need of repair when defects render them inoperable or hazardous to patients. Patient care staff should not repair devices (e.g., nurses should resist the temptation to do a quick fix by application of white tape [Shepherd and Dyro, 1992]). Figure 95-33 shows an attempt to repair a defective latch on the side panel of a radiant warmer. The white adhesive tape, also known as “nurse tape,” lost its adhesive properties when heated by the overhead radiant warmer. The side panel subsequently collapsed, and the infant rolled over the side and fell to the floor. Fortunately, the infant was uninjured by the fall (see Chapter 96 on troubleshooting).

If a device is used in the home, the patient or caregiver is responsible for recognizing the need for repair and for notifying the responsible party (e.g., a durable medical device rental company or manufacturer). The need for repair can be recognized when, for example, the head end of a bed cannot be elevated, the bedside rail binds when raised or lowered, a wheelchair brake does not adequately lock a wheel in place, or screws, nuts or fasteners loosen and cause mechanical instability in the device. As in the case of the hospital-based device above, quick-fix repairs are inadvisable as they often promote a false sense of security. For example, if tape were used to secure an arm pad to a wheelchair frame rather than the proper mechanical fasteners, the arm pad could loosen when subjected to the weight of a patient during a bed-to-wheelchair transfer, and such instability could result in a fall (Figure 95-34).

Modification of a device is deemed appropriate at times when a patient’s needs can best be met by altering the design of the device, especially when alternative device designs are not commercially available. For example, the author has authorized the modification of a hospital bed, thus enabling it to support the weight of an extremely obese patient. Such modification should be undertaken with great care and with the advice and consultation of clinical engineering. The performance and safety of the device must not be degraded as a result of modifications.

Facilities for Service

A well-equipped work space is required for the servicing of general hospital equipment such as beds, stretchers, and wheelchairs. The author incorporated a general hospital-equipment service function into a full-service clinical engineering department (Dyro, 1993). The general mechanics workshop has a two-ton hoist, air evacuation system, welding and refrigeration equipment, standard power hand tools, tool kits, and a complete stock of spare parts, mechanical connectors, and fasteners. The workshop has adequate bench space for three mechanics and a spacious work area. Storage is provided for maintenance and service manuals, which most major manufacturers make available.

Post-Market Surveillance

The clinical engineering department must be part of the hospital’s hazard-and-recall system. Some estimate that the percentage of recalled devices is as low as 4% of those in the field.

Table 95-1 Generalized Medical Device Evaluation Factors

1.	Clinical significance (literature search and historical information)	2.6.2.3	Effect of varying ambient conditions
1.1	Physiologic rationale for device	2.6.2.4	Dependence on patient cooperation
1.2	Statistical incidence and criticality of disease amenable to diagnosis or treatment by the device	2.6.2.5	Calibration requirements

**Figure 95-34** Wheelchair armrests taped to frame.

Inattention to recalls and ignorance of recall and hazard notices may result in defective devices remaining in use in the hospital (see Chapter 139). The clinical engineer has a duty to report to the manufacturer and to the FDA medical devices deemed to be hazardous.

User Education

The manufacturer is responsible for providing adequate instructional material on the proper use of the medical device. Most major manufacturers of beds, stretchers and wheelchairs publish booklets aimed at user, caregiver, and maintainer education (Everest & Jennings, 1989b). The clinical engineering department should maintain a library and should have audio-visual equipment to present educational material (e.g., slides and videotapes) provided by the manufacturer and should play an active role in a hospital's in-service education program (Dyro, 1988).

Obsolescence

Clinical engineering should ensure that a plan is in place to retire general medical devices when their useful lives are over. Well-maintained devices that are retired in favor of newer technology may be considered for donation (see Chapter 43).

Medical Device Troubleshooting

Joseph F. Dyro

President, Biomedical Resource Group
Setauket, NY

Robert L. Morris

Oregon Health & Science University
Portland, OR

The goal of troubleshooting is to repair or correct a fault in an instrument system. This chapter provides a sound introduction to logical troubleshooting of medical devices, medical technology systems, and scientific and analytical instruments. The material presented in the chapter is based upon a general theory of troubleshooting, with stress on general techniques and strategies.

General Approach to Troubleshooting

This section provides a general overview of the process of logical troubleshooting. Other sections delve into the subject in more detail.

Systems Approach

An instrument system consists of three major components: The operator, the environment, and the instrument. A failure in, or poor performance of, an instrument system can be the result of difficulties in any one of the system's three major components.

The operator: The end-user typically makes the initial decision that a failure or malfunction has occurred problems can be due to such factors as incorrect or improper operation, or incorrectly set controls.

The environment: The total environment surrounding the instrument and operator problems can be related to environmental and other factors such as temperature, drafts,

dirt, vibration, incorrect electrical supply, electrical or chemical interference, input exceeding the dynamic range, bad reagents, or bad electrodes.

The instrument: The device that performs a task such as measurement or control. Failures of the device fall into two general categories: (1) non-electric (e.g., loose or broken connections, dirt, corrosion, or mechanical wear. These are the most probable sources of instrument failures); and (2) electronic (a component or circuit failure). In general., the electronic portion of an instrument is the most reliable part.)

The first problem of troubleshooting is to determine whether the fault is in the operation, environment, or instrument component of the instrument system. The purpose of the methodology of troubleshooting is to gather information about the poor performance or failure of an instrument system in a logical and systematic manner. Questions to ask include the following:

- How does the system normally behave?
- What are the conditions of failure?
- What are the symptoms caused by the failure?
- What is the cause of the failure?

Steps in Troubleshooting

- Determine the symptoms and analyze them.
 - Listen, think, look, smell, and operate.
 - Use all available sources of information such as manuals, maintenance records, other people, and the agent or manufacturer.

- State the symptoms as clearly and precisely as possible. Stating that a device does not work, while perhaps true, is not a clear, informative statement of symptoms.
- Localize the problem to a functional module
- Isolate the problem to a circuit
- Locate the specific component or problem.
- Determine the cause of the failure.
- Replace or correct the defective component or problem and correct the causes of the failure.
- Check for correct operation and calibration.
- Complete the record keeping.

Proceed by asking questions and finding answers to them. State questions as simply as possible. Select questions that can be answered easily and that will provide the maximum information to help find the fault. Answer the questions by thinking, observing, and testing. Refer to experts, manufacturers, or agents. Look in manuals, text books, catalogs, or other technical data sources.

Make observations and perform tests, proceeding from the simple to the complex. Think about failure, the degree of failure, the causes of failure, the time course of the failure, and the combinations of failure. In other words, given the information at hand:

- What is most likely to have failed?
- What was the most probable cause of the failure?
- How can the fault and the cause be corrected?

Keep records. Good records immediately help to keep you proceeding in a logical sequence and to keep track of what has been done. Records help in the future by providing a reference in case of additional failures in the same or a similar instrument. They can be used to provide feedback to manufacturers and their agents and to provide management information to aid in making repair or replacement decisions. Records can be used to detect a problem in a particular instrument that might require modification to correct.

Logical Steps in Troubleshooting

The troubleshooting process is the effort to find the discrete element or elements that have failed, starting at the system level and working down to the discrete element. A step-by-step procedure is listed below, adapted from Aston (1990). In troubleshooting, one would follow the steps indicated below until the problem is identified, and then would skip to step 25.

1. Assess the equipment environment with the human senses (i.e., eyes, ears, nose, tongue, hands).
2. Consider operator error.
3. Assess at the system level.
4. Check connections.
5. Isolate the problem device.
6. Verify device operation.
7. Check patient cables, connections, and accessories.
8. Utilize equipment troubleshooting devices.
9. Check diagnostic error messages when available.
10. Execute equipment self-testing procedures.
11. Open case and view interior.
12. Make a module-level assessment.
13. Check all connections.
14. Analyze symptoms for board-level problem isolation.
15. Use specialized diagnostic aids, maintenance manuals, and diagnostic software.
16. Analyze equipment history (e.g., age, preventive maintenance compliance, previous repairs).
17. Analyze data for problem isolation.
18. Consult with manufacturer's technical representative.
19. Make test-point measurements.
20. Analyze data for board-level problem isolation.
21. Take measurements using the device's block diagram.
22. Analyze data for board-level and ancillary-component isolation.
23. Make measurements using module schematic diagrams.
24. Analyze data for component-level problem isolation.
25. When the problem is found and corrected, take action to minimize recurrence (e.g., in-service education, device replacement, or increased preventive maintenance).

Troubleshooter Characteristics and Skills

Characteristics

A good troubleshooter has the following characteristics:

- Curiosity about why things are the way they are, and about how things work, both separately and together
- A thorough grounding in fundamentals, not only electrical, but also mechanical, optical, and chemical
- A good understanding of the general principles, functions, and characteristics of instruments, instrument systems, and computers
- Knowledge of transducers and their characteristics
- Knowledge of the basic components from which instruments are built, such as:

Resistors, capacitors, transformers, inductors, diodes, transistors and other semiconductors, analog and digital integrated circuits, motors, switches, wire, cable, connectors, circuit cards, clutches, and fasteners.

Figure 96-1 General device functional block diagram.

- Knowledge of the failure modes of instruments and components
- Knowledge of their own capabilities (e.g., when to stop and when to ask for help)
- Good manual dexterity
- A systematic, logical approach to problems and problem-solving
- The ability to work well with people

Skills

Troubleshooting requires a broad knowledge base including electronics, physics, chemistry, optics, mechanics, measurement theory, and equipment operation. Troubleshooting requires the following practical skills:

- Careful observation—knowing what to look for, when to look, and where to look
- Effective utilization of instrument service manuals, and other sources of technical data
- Proper use of hand tools and small machinery—using the proper tool or machine for the task at hand, and using them safely and correctly
- Good soldering techniques—using a good, clean soldering iron and following proper practice to prevent damage to delicate components, circuit cards, and insulation
- Knowledge of device assembly, disassembly, and component removal methods—proceeding cautiously and carefully noting the order of things to prevent additional difficulties and to allow proper re-assembly
- Good safety awareness and practices—not only for the trouble shooter but also to note and change those things that could be a hazard to the operator or user of the device

General Description of Instruments

This section presents a general method of describing instruments through the use of functional block diagrams and emphasizing their value in troubleshooting and understanding instruments.

A functional block diagram as a model for any instrument is shown in Figure 96-1.

The functional block diagram can be made more detailed and device-specific, as shown in Figure 96-2.

Further expansion of the functional block diagram is shown in Figure 96-3. This process of expanding a functional block diagram can be repeated to obtain increasing detail and aids in the understanding of the device's operation and possible problem areas. Figure 96-4 shows a device-specific diagram with more detail.

A single block in a functional block diagram of an instrument (e.g., the power supply (see Figure 96-3)) can be broken into its own functional block diagram. The power supply for example would be depicted as in Figure 96-5.

Complete schematic diagrams do not exist for many instruments. There are only functional block diagrams, interconnecting diagrams, and partial schematics. This is true of nearly any instrument that contains integrated circuits. With digital instruments, a logic diagram is furnished. A logic diagram is merely a detailed functional block diagram.

If you understand one instrument, you know something about every instrument. If you understand one type of instrument, such as a spectrophotometer, you know functionally about every instrument that uses or measures light. If you understand functional modules, such as power supplies, amplifiers, you know something about every instrument that includes them. If you understand components, resistors, capacitors, semiconductors, you know something about every instrument that contains those components.

In a functional block diagram of troubleshooting, information is the input; knowledge and understanding is the process; the solution is the output; and the brain is the power supply, as shown in Figure 96-6. As is true with instruments, when the power supply is not working, nothing works well. Instruments and components have more similarities than differences. Knowledge gained by studying one instrument or component can be applied to all instruments and devices.

Figure 96-6 Functional block diagram of a troubleshooting system.

Symptoms and Analysis

This section provides detailed information on the first and most important part of the process of troubleshooting: Determining symptoms and their analysis. The determination and analysis of symptoms are repeated continuously throughout the process of troubleshooting. At each step, localization to a functional module, isolation to a circuit, and locating the defective component, the redetermination and analysis of symptoms through the process of listening, looking, smelling, operating and testing is repeated over and over. Thinking and asking questions to guide the thinking process are essential.

Thought Process

Use the following questions help to guide the thought process as the troubleshooter seeks to identify and learn more about the symptoms of the problem.

- What are the known symptoms?
- Can the symptoms be verified?
- Did the symptoms appear gradually or suddenly?
- Are the symptoms always present?
- Are the symptoms only present under some circumstances (e.g., after warm-up, with certain control settings)
- Are the symptoms only present intermittently and in an unpredictable manner? This is the most difficult case and may require the careful application of thermal, voltage, vibration, or other stress to determine the conditions of failure and to reproduce the failure. Record-keeping of the failure conditions is very important. Interference by another device or system often shows up as an intermittent problem, which is present only when an interference-generating system is operating.
- Are there any other symptoms?
- What is the normal or expected behavior of the instrument?
- How does the actual behavior differ from normal?
- Can the symptoms be restated in a different way that will be more exact and can provide more information?
- What are the easiest checks or tests to perform to verify the symptoms?

When inquiring as to the nature of the problem, formulate and pose easy-to-answer questions that require only yes-or-no answers. The questions should be designed so that an answer can eliminate major portions of the system from further consideration as a potential source of the problem. Examples of these types of questions include the following:

- Did the device ever operate correctly under the conditions to which the failure was attributed?
- Is the device plugged in?
- Is it turned on?
- Is the fuse good?
- Is there an output? Is it normal?
- Is there an input?
- Do the symptoms indicate a possible fault in the power supply or other functional module?

Be flexible with questions. If it is not possible or difficult to answer a question, rephrase it or go on to a different question. Use all available sources of information when analyzing symptoms, and when asking and answering questions. Questions and their answers may be temporary or tentative and subject to change. They are only aids to acquire information so a problem may be solved. They are not the real problem. The direction in troubleshooting is always from the general to the specific, from system to instrument to function to component. The direction in testing is from the simple to the complex.

Looking for Clues

Operate the Controls

- Remember to record the original settings of the controls. The problem could be caused by a control in the incorrect position for proper operation.
- Do all indicator lights (e.g., warning alarms) work properly?
- Do the controls behave normally? Observe device performance and all read-outs and indicators.
- Do the controls look, sound, and feel appropriate?
- Do the controls have an appropriate effect on the operation of the instrument?

Listen, Look, Smell, and Feel

Your senses and brain make up the best and most flexible test and analysis system in the world. Listen to the operator or user, and to the device for normal and abnormal sounds such as:

- Information as to the conditions and symptoms of failure from the operator.
- Rattles, squeaks, buzzes. These can indicate wear or lack of lubrication or motion.
- Sizzling or humming. Either can indicate a short circuit, arcing, high-voltage corona, and excessive loading of transformers.
- Excessive loudness or silence. Each can indicate a broken or defective part such as a cooling fan.

Look for the following:

- Physical damage and wear. (Figure 96-7 shows a bent knob on the front panel of an infant incubator.)
- Loose, inadequate, incorrect, or incompatible connections or connectors. Figure 96-8 shows two connectors on a pressure transducer cable, both of which have bent pins. Investigation revealed that the operator was attempting to connect the cable to the incorrect receptacle on the blood pressure monitor.
- Dirt, dust, lint, corrosion, leaks, or vermin. (Figure 96-9 shows lint accumulation about temperature-control elements in an infant incubator.) Signs of fluid staining also can be seen. Figure 96-10 shows a printed circuit board infested with red ants. The ants apparently were attracted by the tempting odors emanating from the board at the site of power transistor mountings.
- Burned, charred, or discolored insulation, components, circuit cards, or chassis. Figure 96-11 shows a hole and scorch marks produced by electricity from a power cord passing through the chassis of height-adjusting control unit of parallel bars. The cord was inadequately protected with grommet and strain relief.
- Physical relationships—use these to build a mental image of the functional relationships
- Proper mechanical operation—no binding or jerking
- Ways to disassemble the device or module

Smell for the following:

- Overheated transformers. This can indicate a defect in the transformer, an external short, excessive load, or a cooling failure.
- Burned resistors or resistors where you cannot read the color code. These can be caused by reduced value due to age effects, failure of another component or function, or cooling failure.
- Burned or charred insulation. This can be caused by a short circuit, excessive current flow, or an overheated nearby component.

Figure 96-7 Front panel of an infant incubator, showing a bent knob.

Tues, Sept 9, 2003

The 3 cables picture here were picked up by clinical engineering staff from Neurology today. Staff should be reminded that if a connector doesn't seem to fit properly, it should not be forced ... and when one cable doesn't fit, forcing a second or third cable is not a proper response (It also can delay and possibly prevent access to diagnostic data on the patient). Please seek help from other knowledgeable staff or contact clinical engineering for assistance.

The replacement cost of these cables is \$ ____ and this kind of damage cannot be reliably repaired.

Figure 96-8 Bent pins on a connector, resulting from user error.

Figure 96-9 Lint and fluid accumulation on the temperature-control unit of an infant incubator.

Figure 96-10 Ant infestation of printed circuit board.

Figure 96-11 Burns on a chassis caused by a short in the power cord.

Feel for the following:

- Hot spots. Be careful not to get burned or shocked.
- Rough edges or worn spots. These can indicate such things as mechanical wear, incorrect alignment or assembly, or broken parts.
- Smooth operation. Few devices are designed to function in a jerky or irregular manner.

Do not look at schematics or begin taking measurements until you have exhausted the preceding process. Most (nearly 80%) instrument system problems can be solved by using your general and specific understanding of instruments and systems and the knowledge to be gained through a careful utilization of your senses of sight, hearing, smell, and touch.

More Clues—White Tape

White tape—medical adhesive tape—has been properly used for many years to hold catheters in position or to fasten bandages. On occasion, white tape is used inappropriately to make a temporary repair on a medical device. The observation of white tape, or simply the residue of tape previously applied, is a clue in troubleshooting as it reveals that location and the nature of the problem.

Shepherd and Dyro (1982) investigated the uses of white tape. In one instance, white tape covered the plug of a thermistor used on a radiant warmer. Discussions with the nurse determined that, without the tape, the plug had been loose and that the heating of the neonate had been intermittent. The nurse had accomplished a temporary repair that had allowed the device to continue functioning. In another instance, white tape covered a bed-

control plug where it entered a bed. The purpose of the tape was to keep the plug from falling out of its mating connector. On yet another occasion, several layers of white tape were noted as being wrapped around an ECG transmitter. Discussion with a nurse determined that, in the middle of the night, the transmitter had been dropped and the case had become cracked. The nurse had wrapped white tape around the case, and the transmitter had begun working again and had been returned to service. In another instance, white tape was noted at the rear of a device holding a fuse into its fuse post. The fuse cover had been lost or broken, but the tape allowed continued functioning of the device.

Troubleshooting should not be restricted to the laboratory bench and examination of only those devices reported to have failed and brought to the clinical engineering department for repair. The clinical engineer and biomedical engineering technician must be ever vigilant throughout the hospital. The presence of a cracked connector on an ECG cable, a broken meter face on an electrosurgical unit, or white tape on a radiant warmer bassinet latch are signs that underlying problems exist with the devices that may eventually emerge to the detriment of the patient even though the device may appear to be operating satisfactorily.

Shepherd and Dyro (1982) also found white tape used to reduce loud and irritating alarms. In one instance, tape had been placed over the audible output portion of a neonatal warmer to reduce the sound level. In a second case, tape had been placed over a reset button that was normally used to temporarily silence a radiant warmer alarm. The tape held the button "in" so that no alarm could occur. The alarm circuitry was, in effect, permanently reset. A neonate was severely burned by this warmer while the tape was in use. These uses and others have prompted Kermit (1993) to urge tight restrictions on white tape.

Localization, Isolation, and Location

This section continues the process of troubleshooting to localize, isolate, and locate a fault. The general techniques in the above section on symptoms and analysis will be followed. The general sequence to be followed is localization to a function module, isolation to a circuit, and locating the defective component.

- A "function module" is a part of an instrument that performs some major function. Usually, it would correspond to a block in the functional block diagram of an instrument. Examples include power supplies, amplifiers, oscillators, and pre-amplifiers.
- A "circuit" is a part of an instrument that performs an electronic subfunction. It is a part of a function module. Examples include the input stage of an amplifier, the filter of a power supply, the regulator of a power supply, and the output drivers of an amplifier.
- A "component" controls a circuit, current, or voltage. A group of components connected together form a circuit. Examples of components include switches, resistors, capacitors, transformers, transistors, integrated circuits, and lamps.
- Components are used to make circuits. Circuits make up a function module. Function modules make up a device or instrument. Devices can be connected together to make up a system.

Always do the easiest things first. Consider what is most likely to be the problem, and check it first. If the problem is not what you thought it was, stop and think before proceeding. Always be systematic, and record your results so you will know what has been checked and what is known to function correctly.

Localization to a Function

Before a fault can be localized to a function, it is necessary to know what the functions are. One must be able to draw a block diagram. If little is known about the device, the block diagram will be quite simple. As more is learned about the device, a more complete and detailed block diagram can be created. If the trouble is not found after the above symptoms and analysis steps are followed, then do the following:

- Make a decision as to the most probable cause, based on the symptoms.
- Determine what and how to test or measure to verify your decision.
- Proceed in a logical systematic manner so that you will know what you have done and what portions of the device have been found to be functioning correctly.
- Repeat the above process until the trouble has been located, and then correct it.

General Strategies of Testing and Measuring

All other things being equal., it is usually a good idea to check the power supply voltages first.

Substitution: Substitution is often the fastest means of finding a faulty function module, but for it to be effective, several factors must be taken into consideration:

- Think before substituting. The actual fault may be such that it will cause a failure in the substitute. For example, if the 5-volt regulator had failed and the 5-volt supply was actually 8.5 volts, substituting TTL logic cards or integrated circuits would only ruin the substitutes rather than isolate the fault. It is a good idea to check the power supplies before substituting.
- It is generally not a good idea to substitute high-power, current, and/or voltage functional units with high power, as that could damage the power supply and perhaps the substitute.
- The substitute must be known to be working. It is not helpful to replace one broken unit with another.
- When substituting circuit cards, there may be jumpers, switches, or controls on the card that must be set correctly before the substitute will work properly. One example is a memory board in a computer that often has switches or jumpers that must be set to give the correct address to the CPU.

- Substituting a working component for one that has failed can simply create more failed components if the reason for the original failure is not considered and corrected.

Input-to-Output Method: This method involves measuring or testing the input to a functional module. If the measurement is satisfactory, then look at the output of the module. If the output is satisfactory, then the module under test must be good. Move on to the next module.

Output-to-Input Method: This method is the same as the approach above, except that the output is tested first. The choice between the output-to-input method or the input-to-output method is a matter of convenience. Use whichever is easier and quicker.

Half-Split Method: This is a good method to use if there are a large number of identical functional blocks in series or a number of identical circuit cards in an instrument. Test or measure the output from the middle block or circuit card. If the results are correct, then the first half of the blocks are OK, and the problem must lie in the second half. Split the second half of the blocks in half, and measure the signal. If the signal is incorrect, the problem lies between the half and 3/4 block. Further measurements will isolate the problem to a particular block or circuit card. The half-split method is very efficient in searching for a problem in a large number of identical functions that are connected in series. However, several assumptions are made:

- All circuit blocks are equally reliable.
- Only one fault exists.
- All measurements are similar and take the same amount of time.

Most systems do not consist of only series-connected blocks but possess parallel branches and feedback loops. The connections that complicate fault location are:

- *Divergence:* An output from one block feeds two or more other blocks. Check each output in turn, then continue to search for a faulty block in the area that is common to the incorrect inputs.
- *Convergence:* Two or more input lines feeding a single functional block. First, check the inputs at the point of convergence. If all are correct, the fault is beyond the convergence point. If any input is incorrect, the fault must lie in that input circuit.
- *Feedback:* The output of a block that is connected to the input of the same block or to the input of an earlier block.

Feedback systems are more complicated. There are two types of feedback.

Modifying Feedback: Modifying feedback occurs when the feedback is used to modify the characteristics of a system. One example of modifying feedback is the automatic gain control used in radio receivers and video amplifiers. It is often possible to break the feedback loop and to check each circuit inside the loop separately, without a fault signal being fed around the loop. It is usually best to disconnect the feedback loop at the input block. Care must be taken that bias conditions are not upset. In the case of an AC feedback signal, it can be shorted to ground with a suitable capacitor.

Sustaining Feedback: Sustaining feedback occurs when the feedback is essential before any output can exist. Sustaining feedback is used in many position-control systems where a feedback signal, proportional to the position of some output device, is used to cancel the effect of an input signal. Most servo-type chart recorders fit this description. When the feedback is disconnected from the input, it might be possible to inject a suitable signal in place of the feedback and then to check the circuit blocks within the loop.

Isolation, Location, and Cause Determination

Isolation to a circuit within a function is a continuation of the symptoms-and-analysis process, described above. The only additional factor that comes into use is your detailed knowledge of circuits. When isolating to a circuit, it is often useful to look at the schematics, if they are available. Continue to think, look, listen, smell, and feel, and take measurements.

Locating the Defective Component

- Everything that has been said above applies.
- When looking for a faulty component, keep in mind the components that are least reliable and therefore most likely to fail.
- Check the component that is most likely to have failed first.
- Remember to use a systematic approach and to do the easy things first.

When the Fault is Found

Determine the cause of the fault. If the problem is a failed component, determine the cause of failure before replacing the failed component. Replacing a burned-out resistor that was damaged by a shorted transistor will only consume more resistors until the shorted transistor is replaced. Correct the problem, and test the device for proper operation. Review the entire troubleshooting and repair process. Look back at ways in which the problems were found and corrected.

- Were there symptoms that you ignored but that actually would have helped you to find the problem sooner?
- Given similar symptoms, could you find the problem sooner next time?

With the device operating correctly, measure voltages and signals at critical points in the instrument, and record the readings in the manual or on the schematic for future reference. Review the entire process of troubleshooting and repair as a learning experience to find out the things you did correctly and those things that you should do differently. Complete the necessary paperwork to maintain accurate and complete records.

Test Equipment and Tools

This section reviews basic considerations for measurements and the characteristics of common test equipment. The troubleshooter must be thoroughly familiar with the basic principles of measurements and with the test equipment to be used, before the maximum information can be obtained from any measurement performed. One must know what, where, when, how, and why to measure, and must be able to interpret the results of a measurement. Troubleshooting can require a wide range of tools from the basic human senses (eyes, ears, nose, mouth, and hands) to specialized equipment such as ventilator analyzers. Examples of tools that are helpful in troubleshooting are described below.

Measurement

No measurement should be made without knowing, before the measurement, what to expect as a result of the measurement. If you do not know what voltage or signal you should have at a particular point in a circuit, how can you tell whether the results of the measurement are correct or incorrect? The purpose of using test equipment and making measurements while troubleshooting is to gain information about a failure or fault, or about the cause of a failure or fault. The following are definitions of some common terms:

Accuracy: The closeness of a measurement to the "true" or "correct" value. Accuracy is often expressed as a percentage of reading or a percentage of full scale. Digital measuring instruments always have an additional limit on their accuracy of plus or minus one in the least significant digit, due to the nature of digital counting circuits. A known accuracy is the result of calibration.

Precision: The number of significant digits available to describe a measurement. It is usually expressed as a number of digits. For example, the precision of a measurement or instrument can be stated as 5 digits or 3 1/2 digits. Precision does not necessarily imply anything about accuracy. It is possible to build or to buy a digital multimeter that has 4 digits of display but only an 8-bit D/A converter. If that were the case, the precision of such an instrument would be 4 significant digits, but the accuracy could not exceed 0.5%.

Resolution: How finely a measurement can be read or a value resolved. A statement of resolution is usually of the form (referring to the specifications of a DMM) "A resolution of 100 microvolts on the 1-volt range." This statement of resolution implies 4 1/2 or 5 digits of precision. It says nothing about accuracy. Sometimes (particularly when making differential measurements) it will be more important to have high resolution than an accuracy sufficient to match the resolution.

Reproducibility: If repeated measurements of the same signal are taken, how well do the results of successive measurements agree with each other? Reproducibility is affected by the stability of the measuring instrument and the signal source.

Stability: If a stable, unchanging signal is being measured continuously, how stable or unchanging is the indication on the measuring instrument?

Whenever a measurement is made, the use of a measuring device affects whatever is being measured. Most of the effect is due to a change in circuit parameters brought about by the attachment of the probes of a test instrument to a point in the circuit. All electronic or electrical measuring instruments have finite input impedance. Effects might or might not be significant. The effect might be to change the measured quantity so that the result is not useful. Attaching a test instrument to a circuit to make a measurement can change the way a circuit behaves. One example would be trying to measure or to look at the signal at a sensitive point in an oscillator. The process of trying to make a measurement could shift the frequency or could stop the oscillator from oscillating. The consequences of attaching a test lead to a point in a circuit must be considered and understood before the results of the measurement can be interpreted. The effect of attaching a test lead to a point in a circuit is usually called "loading." Loading does not affect the precision or resolution of a measurement, only the accuracy.

Sometimes a measurement is made and it simply is not appropriate. One example would be looking with an oscilloscope or voltmeter directly at the base of a common emitter AC transistor amplifier. The measurement will tell you something about the bias conditions that are present, but very little about the signal. Because a transistor is controlled by current into the base instead of voltage, one probably will not be able to see any signal. If one does see a signal, it will be much smaller than expected.

Yellow Safety Box

The yellow safety box (Dyro, 1995) contains most of the devices and measurement tools that are required in inspecting medical devices (Figure 96-12). Its chief advantage is its portability, which enables the troubleshooting at remote locations. The yellow safety box is particularly applicable to investigating accidents in which people have been injured by medical devices.

A partial listing of the items in the box and their applications follows: Hand tools (pliers, screw drivers, wrenches, hemostats); photometer; digital voltmeter (DVM), sound-level meter; sample collection bags (swabs, plastic bags, brush); measurement devices (letter scale, force gauge, tape measure, electronic tape measure, ruler, micrometer, calipers, protractor; camera (still, moving); tape (white, black, masking); personal protection (gloves, respirator, dusk mask, safety glasses, ear plugs); batteries (AA, AAA, D, C); camera; visual-examination aids (flashlight, headlamp, loop, magnifying glass 5X-30X); markers (pen, pencil); paper (investigation form, graph, ruled, notes, Post-It notes); film (400 ASA 12-, 24-, 36-exposure; video film); candy; and physiologic simulator. (See Chapter 64 for a detailed description of the yellow safety box.)

General Purpose Test Equipment and Tools

Several companies specialize in the manufacture and sale of general purpose test equipment that performs physical measurements such as weight, dimension, pressure and flow, electrical parameters (voltage, current, resistance, frequency, waveform), temperature,

humidity, irradiance, relative humidity, particle count, gas concentration, sound level, time, and force. These companies include Extech, Fluke, Ohaus, Tektronix, Chatillon, and Hewlett-Packard.

A troubleshooting and repair facility should be equipped with a full range of basic hand tools such as screwdrivers, wrenches, pliers, cutters, soldering irons, magnifiers, examination mirrors, drills, hammers, and saws. The list of possible tools is extensive.

Specialized Test Equipment

Many companies (e.g., Metron and DNI Nevada, Inc.) manufacture and sell specialized test instruments designed specifically to test one particular type of medical device or system; e.g., electro-surgical unit analyzers, ventilator testers, defibrillator analyzers, infusion pump analyzers, S_pO₂ analyzers, ECG analyzers, non-invasive blood pressure monitors, fetal monitors, gas analyzers (oxygen, carbon dioxide, nitrous oxide, halogen, ethylene oxide), and electrical safety analyzers.

Several companies manufacture and sell test devices that are specific to their products; e.g., Nellcor (pulse oximeters), Ohmeda (anesthesia machines and infant incubators), and Medtronic (pacemakers and implantable programmable infusion pumps).

Simulators are available to aid in the testing of medical devices. They generally take the place of the patient on whom the medical device is used. These simulators include finger phantoms, test fingers, pulse oximetry, heart rate, blood pressure, ECG, arrhythmia, fetal simulator (ultrasound, maternal ECG, tocodynamometer, beat-to-beat variability), temperature, respiration (impedance), breast phantoms, and lungs.

Many companies are involved in the design, manufacture, sale, and distribution of the above classes of test equipment for use by clinical engineers in the hospital and in the home health care setting. Table 96-1 is a partial listing of some of these companies not mentioned above. Table 96-2 lists most of the test equipment and tools utilized in a full-service clinical engineering department.

Components

All engineers and technicians, whether they are involved in design, troubleshooting, or repair, must know the properties and characteristics of the components used in the electrical and electronic devices with which they are working. In the case of maintenance and repair, a thorough knowledge of components, their characteristics, and their failure modes are important to help in locating and repairing faults also when exact replacement parts are not available and a substitute must be used in its place. Some of the more important characteristics of key components that are relevant to troubleshooting are described in this section.

Resistors

General Characteristics

Power Rating: Common resistors are available in power ratings ranging from 1/8 watt to 10 watts.

- The power rating should never be exceeded.
- The power rating decreases with a rise in ambient temperature. The published power rating usually only applies with an ambient temperature of 20° C and decreases to zero at some temperature, depending on the materials used to fabricate the resistor.
- The power rating of a resistor used in a circuit should be at least twice that of any required power dissipation. This usually will provide a sufficient safety margin to prevent premature failure.

Tolerance: Resistors come in standard tolerances of 3%, 5%, 10%, and 20% (seldom used anymore). A resistor will only remain within its accuracy tolerance if it has not been placed under stress through exceeding its power, temperature, or voltage limits.

Temperature Coefficient and Temperature Range: The value of a resistor will change with temperature. The amount of change is dependent upon the materials from which the resistor was fabricated. Some resistors will return to (or near) their original value when the temperature is reduced, and some will exhibit a hysteresis effect.

Figure 96-12 Yellow safety box (Dyro, 1995).

Table 96-1 Test equipment manufacturers (partial listing)

<i>Test Equipment Manufacturers</i>			
Anlor	Bio-Tek Instruments	Manley Lung Simulator	Riken
Bacharach	Clinical Dynamics	Mini-OX	TIF
BAPCO	ComfortCheck	Netech Corporation	Timeter
BC Biomedical	Dale	Nuclear Associates	TSI
BC Group International, Inc	Mallinckrodt	Ohmic	UMA

Table 96-2 Clinical engineering department test equipment and tools

Anesthesia test equipment	Anesthetic gas analyzers	Cable and LAN testers
Cases, carts, and dollies	Conductivity meters	Defibrillator analyzers
Despound meters	Diathermy analyzers	Electrical safety analyzers
ESU analyzers	Endoscopy test equipment	Environmental test equipment
ESD/static straps, and mats	Fetal monitor simulator	Flowmeters
Halogen leak detectors	Humidity meters	Infusion pump testers
Laser power meters	Leads and probes	Light meters
LIM/GFI testers	MAS meters	Medical gas analyzers
Miscellaneous testers	Miscellaneous hand tools	Multimeters
Nitrous oxide monitors	NIBP simulators	Non-magnetic tools
Oscilloscopes	Oxygen analyzers	Pacemaker analyzers
Patient simulators	Phototherapy radiometers	Power line and EMF monitors
Power supplies	Pressure meters and gauges	Pulse oximetry simulators
Radiation dosimeters	Sound level meters	Tachometers
Temperature meters	Ultrasound wattmeters	Ventilator testers
Weights and balances	Workbenches and furniture	Imaging phantoms

Voltage Rating: Resistors have a voltage rating which must not be exceeded or permanent damage to the resistor will result. The voltage rating is a maximum even if the power rating of the resistor is not exceeded.

Linearity or Taper (Variable Resistors): How the resistance varies with wiper position is an important parameter. Most potentiometers used in audio circuits as level or volume controls have a log taper because the ear responds logarithmically to sound levels. Power ratings apply when the power is dissipated throughout the entire resistive element. Variable resistors connected as rheostats are easy to burn out if the rated power is dissipated in a small portion of the element.

Fixed Resistors

Carbon Composition: Composition resistors are made of carbon particles in a binder material that is pressed into shape. The most common failure modes are the following:

- High in value. Caused by migration of carbon or binder under heat, voltage, or moisture. Absorption of moisture causes swelling, thus forcing the carbon particles to separate.
- Open Circuit. Caused primarily by excessive temperature. Carbon composition resistors decrease in value with temperature. Some do not return to their original value when cooled and their values slowly decrease with age until they short and then burn open.

Carbon Film Resistors: Carbon film resistors are made by depositing a carbon film on a ceramic tube. The film is usually in the form of a spiral on the outside of the ceramic base. It is covered with a paint to seal it from moisture and the outside world. The most common failure modes are:

- Open Circuit. Caused by disintegration of the film due to high temperatures. Film also can be scratched or chipped.
- High Noise. Caused by bad contact of the end connectors. It is usually the result of mechanical stress caused by poor assembly in a circuit.

Metal Film Resistors: Manufactured the same way as carbon film but using a metal film as the resistive element. Metal film resistors are more temperature-stable and age more slowly than carbon composition or carbon film resistors. The failure modes for metal film resistors are the same as for carbon film.

Wire-Wound Resistors: Wire wound resistors are made by winding a wire on a ceramic tube and covering it with a ceramic paint. Wire-wound resistors are used where high power dissipation is required. Their principle failure mode is open circuit caused by a fracture of the wire, especially when fine wire is used, and by progressive crystallization of the wire due to impurities. The failure also can be caused by corrosion due to absorbed moisture. Wire-wound resistors also open due to a failure in the welded end connection.

Variable Resistors

Partial failures such as a rise in wiper contact resistance causing noise are common. This is usually caused by dust, grease, or other material trapped on the element. Excessive noise also can be caused by wear of the resistive element. Open-circuit failures are due to corrosion, moisture, high temperatures, or wear from the wiper sliding on the resistive element.

Capacitors

Capacitors come in many shapes and sizes. They are classified into two major categories: Polar and nonpolar.

Polar Capacitors

Polar capacitors are sensitive to the polarity of DC voltages applied to them. They are further classified by the metal used for the anode. Polar or electrolytic capacitors have a much higher capacitance-to-volume ratio than do nonpolar capacitors. Polar capacitors have wide tolerances. Their capacitance varies dramatically with temperature, voltage, current, and frequency. Most electrolytics become inductive at frequencies above a few hundred kilohertz.

Aluminum is the most common material used to make polar or electrolytic capacitors, which are relatively inexpensive and are used mostly as power supply filters. Reversing the voltage across an electrolytic capacitor will usually cause a short circuit and will destroy the capacitor, due to overheating the electrolyte. The capacitor can explode when subjected to reverse currents or to AC voltages.

It is a characteristic of aluminum electrolytic capacitors that the DC voltage rating will deteriorate with time. In a circuit, the voltage rating will gradually fall to the value required by the circuit. If a large voltage spike occurs on an old aluminum electrolytic capacitor, it can cause a short and failure of the capacitor even though the amplitude of the spike is less than the voltage rating of the capacitor.

When stored on a shelf, the voltage rating of an aluminum electrolytic capacitor will gradually decrease towards zero volts. The voltage rating can be restored through a process called "forming." A voltage is applied to the capacitor through a resistor (to limit the current) until the current drops to a reasonable value. The capacitor then will have a voltage rating equal to the applied voltage.

Electrolytic capacitors have a liquid electrolyte that forms the cathode or negative side of the capacitor. This electrolyte tends to dry out with age, ruining the capacitor. Overheating the capacitor can cause the electrolyte to leak out through the pressure seal and can cause the electrolyte to dry out.

The best way to check an electrolytic capacitor is by substitution. If the capacitor has failed open circuit or has decreased in capacitance, it can be checked very quickly by putting another capacitor in parallel. Many so-called capacitance checkers cannot effectively check electrolytic capacitors. Electrolytic capacitors often fail or require replacement because of an increase in their equivalent series resistance. Most capacitor checkers do not measure the equivalent series resistance of the capacitors they check.

Tantalum electrolytic capacitors use tantalum as the anode material. Tantalum capacitors have a higher capacitance-to-volume ratio, lower leakage, and a higher reliability than aluminum electrolytics. Tantalum electrolytics are also more expensive than aluminum. They are not made with voltage ratings above approximately 50 volts.

Nonpolar Capacitors

Nonpolar capacitors are not sensitive to the polarity of applied voltage. They are classified by the material used as a dielectric.

- Paper foil capacitors are very common in older instruments but are seldom used anymore. They have been replaced by plastic film capacitors. Paper capacitors tend to fail short circuit or intermittent open circuit.
- Ceramic capacitors have fairly good high-frequency characteristics. They do not have good capacitance stability and are usually used in circuits where the actual value of capacitance is not critical, such as for bypass. Ceramic capacitors can fail open circuit, short circuit, or intermittent open circuit.
- Plastic film capacitors are made using many different kinds of plastic film. Mylar and polystyrene are the most common materials used. Plastic capacitors are the most common type used in building electronic circuits. When they fail, it is almost always as an open circuit. This makes it easy to check by merely tacking another capacitor in parallel to see whether the problem has been corrected.
- Mica capacitors are very stable in value and have excellent high-frequency characteristics. They are not made with capacitance values above 0.01 microfarads. They tend to fail by short circuit or intermittent open circuit.
- Oil-filled capacitors are used primarily for motor start or run, energy storage, and power-factor correction and phase shifting of AC voltages. Oil-filled capacitors are available with capacitance values from 0.001 to 50 microfarads. They tend to be physically large, and they usually fail through leakage of the oil dielectric. The oil used, particularly in units manufactured prior to 1973, might contain polychlorinated biphenyl (PCB), which can cause cancer following prolonged exposure.

Semiconductors

Diodes

Diodes are semiconductor devices that have only one junction. Current will flow in only one direction. Diodes can fail open or shorted. There are many types:

- **Power diodes or rectifiers:** These diodes are characterized by their high current and voltage ratings. They are most commonly used as rectifiers in power supplies or other applications that require relatively high currents.
- **Signal diodes:** Signal diodes are physically smaller than rectifier diodes and have lower voltage and/or current ratings. Signal diodes have a much lower junction capacitance, allowing them to be used for higher frequencies and in switching applications.
- There are many other kinds of diodes, such as light-emitting diodes (LED) and Zener diodes.

Transistors

Transistors are three-terminal devices that contain two or more junctions. They are available in many different packages, with different voltage, current, and power ratings, and with different polarities. They typically fail at the junctions. The junction can become

either open circuit or short circuit, although short circuit failures are more common in high-power transistors. Failures can be caused for the following reasons:

- The manufacturing process. Most of these defects will be picked up during the various quality control checks and tests performed during manufacture. Some units will possess defects that will cause premature failure in equipment.
- Most failures are caused by misuse; bad handling practices; excessive power, voltage, or current ratings; or overheating. Many transistors, and most integrated circuits, will be damaged if they are removed from, or inserted into, a circuit with power on.
- Static electricity is an important source of failures in all types of semiconductors, but especially in MOSFET devices. Proper precautions must be followed during shipping, storage, handling, insertion, removal, and soldering.

Integrated Circuits

In general, all of the comments for transistors apply to integrated circuits (ICs). Because of the number of pins, care must be exercised in removing an integrated circuit, to prevent damage to the integrated circuit, the remainder of the circuit, or the printed circuit card. Particular caution is necessary when the IC is not in a socket and must be unsoldered. The IC can be easily damaged by excess heat from a soldering iron while soldering it to, or removing it from, a circuit card. In general, integrated circuits are more susceptible to damage from static electricity than are transistors. MOS integrated circuits are especially vulnerable to damage.

Fuses

Fuses are two terminal devices that are present in nearly every instrument. The purpose of fuses is to protect against fires and/or consequential damage in an instrument due to a circuit or component failure within the instrument. Fuses are unique among electronic components because a fuse can be said to have performed correctly when it fails, blows, or open-circuits. When a fuse has performed its function, it must be replaced.

A number of parameters characterize fuses:

- **Current rating:** The value of current through the fuse, which, if exceeded, will cause the fuse element to melt or to soften, and the fuse to open-circuit.
- **Speed:** How long after the current rating of the fuse is equaled or exceeded will it open-circuit? Fuses are classed into two major speed categories: "fast-blow" and "slow-blow." There are many variations, ranging from "ultra-fast-blow" to "long-delay."
- **Voltage Rating:** Fuses are voltage-rated by the amount of voltage that can be reliably interrupted by the fuse when it opens. When a fuse opens, the voltage that can appear across the fuse can cause an arc to form, which can maintain electrical continuity. The arc must not be maintained because the circuit can open and prevent further current flow.

Circuit breakers are the functional combination of a fuse and a switch. They have the advantage over a fuse of being able to be reset. When the current rating of a circuit breaker is exceeded, a switch is automatically opened which breaks the circuit. The switch can be manually actuated, and the circuit breaker reset to again perform its function. It does not need to be replaced after functioning as a fuse does. Circuit breakers are designed with one of two actuating mechanisms; thermal and magnetic.

- **Thermal:** In a thermal circuit breaker, the current through the breaker passes through a heater, which activates the switch portion if a certain temperature is exceeded.
- **Magnetic:** In a magnetic circuit breaker, the magnetic field caused by the current through the breaker will activate the switch part of the breaker if it exceeds a preset value.
- Magnetic circuit breakers operate much more quickly than do thermal circuit breakers. A thermal breaker may require 0.2 to 0.5 seconds to open, while a magnetic circuit breaker will open in 0.05 seconds under the same conditions.

Fuses and circuit breakers will change their ratings and characteristics, depending upon ambient operating temperature, vibration, age, and other environmental factors. Circuit breakers—especially thermal breakers—will change their ratings after repeated actuations. It is important to replace a fuse or breaker with one of the same characteristics. It is particularly bad to replace a fast-blow or regular fuse with a slow-blow type. Serious circuit damage can result because of the longer actuating time.

Microprocessors

Many modern instruments include a microprocessor and associated circuits. It is important that the troubleshooter have some knowledge of how to locate and correct faults in these instruments. It is also important that spare specialized circuits, such as ROMs, be purchased at the same time as the original instrument because such parts might not be available later, or might be manufactured to different specifications. There is an increased emphasis on data communications systems and instrumentation, including short- and long-distance systems. There will be significant improvements in maintainability and built-in diagnostic programs. These will aid the operator and the troubleshooter. Built-in diagnostics are only useful if and when the microprocessor itself is functioning. The following faults can prevent diagnostics from being helpful: No power, or a faulty power supply; faulty clock; faulty ROM; or faulty peripheral integrated circuit or function.

Troubleshooting and Repair Strategies

The optimal strategy for troubleshooting and repairing microprocessor-based instruments depends on several factors, such as:

- How much is known about the instrument, its microprocessor, and associated software
- Available manuals or documentation

- Available test equipment
- Available spare parts
- Available information from the local agent or manufacturer

There are certain rules or methods of troubleshooting and that are always correct:

- Check and correct any problems that may exist in the power supplies.
- Diagnostics that are built into the equipment should be exercised to see whether any problems can be detected.
- Substitution of components or sub assemblies is a good, rapid technique, but it requires spare parts that are known to be good.

If nothing works, check the following:

- Power supplies
- Clock system
- Program memory (ROM)
- Address bits (for toggling)

Signals always should be measured at the IC pins, not on the circuit card or connectors, when verifying that an IC works or when checking power supplies. By following the simple guidelines outlined above, most microprocessor-based equipment problems can be solved. Those that cannot be solved through the above process usually require extensive testing and analysis.

Interference and Noise

This section concerns the problems of interference and noise. No other area of troubleshooting causes so much difficulty for the average troubleshooter or is as difficult to find and correct. One reason for the difficulty is that the source of the noise or interference might be external to the device under test and might not be present in the test and repair area. The source may also be intermittent. Noise and interference problems can be classed as internal or external and are treated in different ways.

Internal

Internal interference and noise occur when the source of the interference or noise is within the instrument. It can be caused by component failure and mechanical factors such as loose connections and improper routing of wires. Many types of component failure can inject large amounts of noise into a circuit:

- Film resistors
- Paper, ceramic, or mica capacitors
- Dust or other foreign material under the wiper of a variable resistor
- Semiconductors (In some instruments, a semiconductor junction is deliberately used as a source of noise)
- Linear integrated circuits sometimes produce what is called "shot noise" or "popcorn noise."
- Connectors age, become corroded, collect dust and dirt, and lose contact pressure.
- Switches suffer from the same problems as connectors.

Mechanical sources of interference and noise include the following:

- Broken or loose wires or connections.
- Loose bolts or screws that hold the instrument together (particularly if there are small differences in potential between the two parts of the instrument or if the two parts rub together)
- Static electricity generated by loose connections and the rubbing contact between two dissimilar materials
- Misrouted signal or power leads. In general, signal leads should be kept separate from power leads, and low-level signal leads should be kept separate from high-level signal leads or sources.
- Dust or sharp points in a high-voltage circuit causing corona discharge
- Missing panels, shields, and grounding connections

Finding the internal source of the interference and noise and correcting the problem is much easier said than done. The following steps should be taken:

- If the source within the instrument is unknown, the best approach is first to go through the instrument very carefully, tightening all loose screws and connections.
- Wiggle cables, connections, and circuit cards and rap on panels while observing the occurrence of the noise. Be careful not to wiggle things too much or to tap them too hard. You could cause more problems than you solve.
- Clean all dirt and dust from the instrument. Pay particular attention to those areas where high voltage is present.
- Carefully inspect, clean, and observe the operation of any switches or relay contacts that are switching high power or voltage.
- Carefully observe the noise or interference with an oscilloscope. Try to define the characteristics of the unwanted signal.
 - Is it related in frequency, repetition rate, period, or in some other way, to a legitimate signal generated within the instrument?
 - Does the instrument have a switching power supply or regulator? Is the noise or interference related to the switching frequency?
 - Is the noise or interference related to any signal with which you are familiar, such as the mains frequency, twice the mains frequency, or the vertical or horizontal rate of a raster scan CRT?
- Try to isolate the source to a function, section, or circuit.

- If the noise is present on the power distribution lines, carefully check the capacitors in the power supply. There should be a ceramic or other capacitor with good high-frequency characteristics, in parallel with the main filter electrolytics because aluminum electrolytic capacitors become inductors at frequencies above a few hundred kilohertz. The impedance rises with further increase in frequency.
- Carefully check the bypass capacitors in any circuit that generates high-frequency or high-amplitude signals.

External

External interference or noise occurs when the source of the interference or noise is external to the instrument under test. The external source could be any of the following:

- Interference or noise conducted through the mains
- Interference or noise radiated through the air
- Interference or noise due to varying electric or magnetic fields in the vicinity of the instrument
- Interference or noise generated by other instruments in the vicinity

Elimination of problems due to external interference can be accomplished using three general techniques:

- Modifying the sensitive devices to make it less sensitive to the interference. This can be done through shielding, filtering, or grounding.
- Modifying the source of the interference to reduce the amount of interference generated or transmitted. This is done through appropriate shielding, filtering, and grounding.
- Moving either the source of the interference or the sensitive device to a location where the problem no longer occurs.

Interference or noise also can be caused by connecting two or more instruments. The most common reason is current flow in a ground loop. Ground loops occur when two or more devices are connected together in such a way that there is more than one connection to ground. The multiple connections form a loop through which current can flow if there is a potential difference between points in the loop. Because the resistance around a ground loop is very small, only small potential differences are needed, to cause large currents to flow. These currents generate magnetic fields that create the interference. Many times, all ground loops cannot be eliminated in actual practice. Actually, the problem is not that a ground loop exists—problems only occur when a current flows in the loop. If the current is reduced in a ground loop, the interference is also reduced. Often it is possible to insert a small-value resistor (15–50 Ohms) in the loop. This usually will reduce the current so that there will be no harmful interference.

Avoiding More Trouble

This section provides information to prevent any additions to the already difficult job of troubleshooting. The areas of concern are primarily mechanical, electrical, and measurement.

Mechanical

The Right Tool for the Job

During disassembly and assembly of an instrument, use the proper tool for the job. Use of an incorrect tool can cause damage that will prevent the removal of a screw or component, or it can cause unsightly damage such as burrs or scratches. For example, there are at least three types of cross-point screws.

- *Phillips*: It is identifiable because the screw head indentation has a flat bottom, and the driver also has a flat tip. This is the most common type of crosspoint screw.
- *Pearson*: It looks just like the Phillips, except that the screw head indentation has a pointed bottom, and the driver has a pointed tip.
- *Posi-Drive*: The tip of the screwdriver has a convex curvature to match the screw head. The screw head is identifiable by the extra lines between the indentations. This type of screw is used on all Hewlett-Packard and Tektronix equipment.

Screwdrivers and screws come in many sizes. Use the proper size driver for the screw. Screws and nuts are often very tight and will not come loose easily. Several techniques can be used to loosen the screw. Clean the head of the screw. Place a proper size screwdriver firmly in the screw head and give a quick snap of the wrist. This often will loosen an otherwise impossible screw. If the screw still will not loosen, tap the end of the screwdriver handle with a hammer, and then try again with a snap of the wrist to loosen the screw. Apply torque to the screwdriver while tapping it with the hammer. Apply a penetrating oil or solvent and allow it to soak, and then try again to loosen the screw. If the screw has been set with a varnish, shellac, or other substance to prevent loosening, heat it with a soldering iron, and then try to loosen it while it is still warm.

Needle-nose pliers are not made for use as a wrench or spanner to tighten or loosen bolts and nuts. In general, pliers are not manufactured to use as spanners. They mark up the nuts and bolts so that a proper spanner will no longer fit.

Wire-cutting diagonal pliers should not be used to cut steel wire or small screws and bolts. The jaws are not made to cut materials harder than copper alloys. Special cutting pliers are made to cut steel.

There are many different type of hammers. The reason is that each type is designed to be used for a particular purpose. Certain hammers are designed to be used to strike steel, while others are made to pound nails. Pounding steel with a hammer that is designed for

pounding nails is very dangerous, as the head could shatter or chip, tossing bits of the steel hammer head about. Workers have been blinded by use of the wrong hammer.

Physical Relationships and Alignments

Use caution when taking something apart, especially if you are not familiar with the device. Clear your work bench and surroundings of all non-essential material, tools, and equipment. Observe carefully, and think before you begin disassembly. Determine how it comes apart, and the tools that are needed. If there are springs or other small parts that could be easily lost or misplaced, they should be placed in a small container. Scratch or scribe a mark across the crack between parts before taking them apart. This will allow re-assembly keeping the original alignment. It is an especially valuable technique to use when taking apart motors or other devices with cylindrical symmetry. When disassembling a device, it is helpful to lay the parts out on a clear area of your work bench in the same order in which they are removed. Most things will go back together in the reverse order of disassembly and this approach will allow you to remember the order.

Electrical

There are three major causes of electrical problems that can add to your difficulties: Static, transients, and short circuits.

Static

Static electricity causes far more damage than most people realize. The average person has a capacitance of between 250 and 500 picofarads. It is easy to collect sufficient static charge to generate voltages from 5–20 kilovolts equivalent to a stored energy ranging from 3–100 millijoules. That much energy dissipated in a short-duration discharge is sufficient to damage most low- or medium-power semiconductor junctions. Most engineers are aware that static electricity can damage MOS and CMOS devices, but it is important to realize that bipolar devices such as TTL integrated circuits, operational amplifiers, and bipolar transistors also can be damaged.

While static discharge will usually destroy MOS devices, the damage done to bipolar devices is generally not so obvious. The discharge usually results in a weakened junction, which will fail later under normal voltage or thermal stresses. Transistors often exhibit low, unstable, or very non-linear betas after being subjected to static discharge. Static electricity is especially bothersome when the relative humidity is below 40%.

The best way to prevent static damage is to be aware and to prevent build-up of voltage differences due to static electricity. The following guidelines should be followed to minimize the risk of static electricity:

- Store and transport static-sensitive devices in conductive containers. Do not store integrated circuits and transistors in plastic drawers, or stick them into white styrofoam plastic.
- If possible, have an area of your workspace set up with conductive bench surfaces and floor mats.
- Provide a wrist strap or other means to refer yourself to a ground potential.
- The conductive bench surface and floor mat and the wrist strap should not be connected directly to a ground point. Connection should be made through a 100-kilo-ohm resistor to ground. This will allow enough to bleed off static charge, but high enough to prevent a shock hazard if you come in contact with high voltages in the device under test.
- When handling dual-in-line integrated circuits, grasp them with your fingers on the ends of the package. Do not touch the pins unless it is necessary to do so.
- Use a grounded-tip soldering iron.
- While a device that is mounted on a circuit card is generally less sensitive to static electricity, it is not always so, and semiconductors can be damaged even though mounted in a circuit card.

Transients

Spikes, glitches, or other voltage and current transients can cause component failure. They usually occur as the result of switching or sudden changes in voltages and currents.

- Do not plug or unplug components with power applied to the circuit.
- Do not remove or insert printed circuit cards with power turned on.
- Beware of inductive transients. They can be caused by such things as motors, relays, and transformers, that are either not provided a means to dissipate magnetic-field energy when turned on or off, or the protective devices provided have failed.

Short Circuits

Inadvertent short circuits can be caused by the following:

- Bending together or shorting two points while removing panels, gaining access to a circuit, or replacing a component, or while making measurements
- Using an incorrect tool or using a tool inappropriately
- Slipping with a probe while making a measurement or while attaching the probe
- Spilling liquid on or into an instrument or device

Accidental short circuits can be prevented by observing the following rules:

- Be careful.
- Turn the power off while attaching test probes.
- Use the proper probe tip. Do not attempt to measure at the pins of an integrated circuit with a blunt probe. It is too easy to slip.
- Do not have coffee, tea, coke, or other unnecessary liquids nearby when working on electrical or electronic equipment.

Measurements

Problems caused by measurements fall into three categories: Improper tools, improper measurements, and improper measurement technique.

Improper Tools

When taking measurements, it is important to use the proper probe or probe tip. For example, without the proper probe tip, it is very difficult to take measurements from the back of a wire-wrapped circuit card. On many circuit cards, spacing is very close, and it is almost impossible to prevent an inappropriate test probe from contacting more than one point at a time.

- Use the proper probe.
- Use aids such as a clip to go on dual-in-line integrated circuits to make the pins more accessible.
- In some cases, it may be necessary to solder a lead to a point in the circuit to gain access for a measurement, particularly if you do not have an extender card to use.
- Extender cards and cables can be very helpful. Remember that extender cards usually do not have keys to ensure that the component side of a circuit card is facing the correct direction.

Improper Measurement Technique

In the case of an improper measurement technique, the idea of the measurement is correct, but the measurement is made in such a way that the fault is not detected or apparent. For example, if an electronic regulated power supply output is measured under no-load conditions, the output can appear correct even if there is a base-emitter short in the series-pass transistor. To detect the problem, the power supply must be loaded. Extender cards will change the electrical characteristics of a high-speed, digital, low-level analog, or any other system or circuit where lead length is important. Under these conditions, extender cards might not be very useful.

Safety

This section is about safety: Safety for the troubleshooter, safety for the equipment operator, and safety for the patient in the case of medical equipment. There are many ways in which one could be injured while working on or around instruments and equipment. The sources of hazards can be classified as electrical, mechanical, radiation, burns, or biological.

Electrical Hazards

Physiological Effects

Electrical current does the damage. Currents less than 500 microamperes produce no sensation or feeling. Sensory nerves are stimulated at current levels of 500 microamperes to 2 milliamperes. Above 2 milliamperes, the motor nerves are stimulated, and muscles contract. Above 1 ampere, burns are likely as a result of the power losses and heat generation in tissue.

Electrical sensitivity is a function of frequency. The frequency to which humans and other biological systems are most sensitive lies in the range of 50 to 60 Hertz. At frequencies above and below this range, more current is required before any sensation is felt, and more current is required to stop the heart from beating.

Most injuries from electric shock are trauma injuries or burns. The trauma results from the "startle reaction" or sudden muscle contractions. For an electrical shock to occur, three conditions must be met: (1) there must be a difference of potential; (2) there must be a path for current flow; and (3) sufficient current must flow.

Safety Rules to Prevent Electrical Shock

- If possible, turn off all power while working inside an instrument, when removing covers and panels, when attaching a probe to a high-voltage test point, when working in tight quarters, and whenever you leave a device with exposed high voltage.
- If power must be on, use only one hand. Keep the other hand in your pocket, where it cannot contact another part of the system to provide a path for current through you. There must be a path for current and a voltage difference before an electrical shock can occur.
- Interlocks are designed for a purpose. Carefully consider the safety consequences before defeating interlocks.
- Use insulated tools whenever and wherever possible.

The purpose of the third or "ground" wire in an instrument's power cord is to protect the user or handler of the equipment from electric shock. Using ungrounded devices increases the risk of electric shock. It is important to realize that the equipment will operate perfectly well without the ground wire intact. The only way to tell whether a device is grounded is to measure continuity from the ground pin of the power plug to the chassis.

Mechanical Hazards

Power Tools

Electric power tools such as drills, grinders, and saws can be dangerous. Clamp your work when using a drill press. Protect your eyes from flying metal chips and glass. Beware of sharp edges that can cut you. Do not defeat the guards and shields that are provided for

protection. Use protective clothing, face shields, or other protective equipment. Most importantly, use tools and equipment correctly.

Compressed Gas Cylinders

Compressed gas cylinders are potentially very dangerous devices. When filled at high pressure, a relatively light blow can turn the cylinder into a rocket with enough power to go through a concrete wall. Gas cylinders should always be secured so that they cannot fall over. They also should be protected from sharp blows.

Lifting

Lift carefully and properly. Back injuries can be permanent. Do not attempt to lift too much. Find help. Be especially careful when lifting awkward or odd-shaped items or when lifting any object over your head.

Radiation Hazards

Non-Ionizing Radiation

Radio frequencies, microwaves, and visible and ultraviolet light are forms of non-ionizing radiation. The principle effect is a burn of some type. Radio frequencies and microwaves can cause serious burns that show up as a small hole in the skin but cause a larger damaged volume beneath the skin. Such burns heal very slowly and have a high probability of becoming infected.

Damage to the eyes often shows up as cataracts, which can cause blindness. Cataracts might not form until years after exposure. Many scientific instruments use or contain a light source. The source might be infrared, visible, or ultraviolet; gas discharge, arc, incandescent, or laser. Many of these light sources are very intense or bright and can cause serious and permanent eye damage. Most people are aware of the dangers of ultraviolet light, but the infrared wave lengths are equally dangerous to the eyes. Always protect your and your fellow workers' eyes when working on instruments that include lasers or other light sources.

Ionizing Radiation

Ionizing radiation cannot be seen, heard, smelled, or felt. One must depend upon instruments to detect its presence. Always wear film badges or other means of detection and dose measurement while working around X-ray machines. Do not go into a room while an X-ray is operating without suitable protective clothing. When working with radioactivity, beware of contamination or spills.

Some instruments use potentially dangerous amounts of radioactivity as a part of them. Examples include a cobalt therapy unit and an ionization detector, used in many gas chromatographic instruments. Some high-current, high-voltage electronic switches contain a radioactive source to stabilize their turn-on characteristics. If these switches are broken, hazardous amounts of radioactivity can be released.

Sound Radiation

High-intensity sound can cause permanent hearing loss and tinnitus (ringing in the ears). Many ultrasonic devices (particularly large, ultrasonic cleaners and ultrasonic disintegrators used to disrupt cells in biological research) have sufficient power output to cause headaches or other problems. Use ear plugs. Putting cotton in your ears is better than nothing.

Other Hazards

Burn Hazards

These are mostly self-explanatory. Hot soldering irons, vacuum tubes, heaters, lamps, motors, power resistors, and heat sinks all can cause painful burns. The rule is to think and beware of all things hot.

Biological Hazards

These hazards apply only for some medical equipment, such as dialysis apparatus, surgical devices, and patient monitors, which have been used on patients who have infectious diseases. If you have a medical device that has blood on it, assume that it is potentially infectious. Clean it before doing any troubleshooting or repair. Use gloves and other protective clothing. One common instrument, which often contains a biological hazard, is a centrifuge. The inside of the bowl is often coated with material from centrifuge tubes that have broken while spinning.

It is the responsibility of the repair person to ensure that a device that is repaired and returned for use is safe to operate. This means that all interlocks are operations, that all protective shields or guards are in place and functioning, and that there are no exposed electrical wires to shock the operator.

Patients are a special class of equipment user. They often are not aware of hazards and cannot move themselves. Patients do not know that they are not supposed to be shocked by a medical device. They often are much more susceptible to injury than well persons are. Patients with heart disease are much more likely to suffer damage from an electric shock than are well persons.

Conclusion

There are no deep, dark secrets to effective troubleshooting. Troubleshooting is the process of applying what you already know, in a logical, systematic manner, to acquire

the necessary additional information to find and correct faults in scientific instruments. The most important troubleshooting device is the troubleshooter's brain and senses of sight, hearing, smell, and touch. The most important thing to remember in troubleshooting is to be logical and systematic. Stop, think, and plan your approach. The most common cause of electronic failure is heat and high temperatures. The most common cause of overheating is dirt, dust, or other material covering components, circuits, or instruments affecting heat transfer and airflow characteristics.

Keeping instruments clean is the best way to reduce the frequency of failure. Many faults are non-electronic. The failures might be due to mechanical failure; broken wires, connections, or parts; loose or missing screws, bolts, connectors, or fasteners; or worn or misaligned parts. Remember to always look and think and do the easy things first.

Work from the outside of the instrument, in. Learn all you can from the outside. A careful visual inspection, while keeping the description of the fault in mind, is a useful guide. Look, think, and operate. Look for obvious, simple, potential causes of the problem first. Keep the functional block diagram in mind to help guide you in your search for the problem. Your senses and brain are the best troubleshooting combination.

Do not refer to schematics or take measurements until you have used your senses as far as possible. When measurements or other tests are required, do the simplest or fastest ones first. Do not take any measurements if you do not know what the result of the measurement should be. When looking for faults or a faulty component, look for those that are most likely. Keep in mind the failure rates and failure modes of the components, modules, and instruments.

Be sure that all connections are clean and making good electrical contact. In instruments that have external electrodes or transducers, the most likely failures and the parts to check first (after careful visual inspection) are the electrodes, transducers, and cables.

Do not forget to complete the paper work. It is important. After the repair is complete, review the entire troubleshooting and repair process, going over each step that was taken. Ask yourself whether the process you took was the most efficient or the best under the circumstances. Would you attack the problem the same way if you had another instrument with similar symptoms? What did you learn from the entire process?

Section IX

Information

Elliot B. Sloane

Assistant Professor, Department of Decision and Information Technology, Villanova University
Villanova, PA

This section is devoted to the profound and important transformational role of computers and information systems (IS) in health care in general, and on the clinical engineering profession in particular. Clinical engineers, who apply technology to improve patient care, need to redefine their relationship to computers and IS. Prior conceptions of IS as business and scientific technologies must yield to a new appreciation for the unique and valuable contributions that they continue to make to patient care. Clinical engineers who do not understand (or who avoid) this conclusion may find their circles of influence and activities rapidly diminishing. The information in this section is intended to help avoid that fate by briefly reviewing the past and then illustrating why topics like Y2K and the Health Insurance Portability and Accountability Act (HIPAA) are important in the successful evolution of computers from technical, administrative, and financial tools to invaluable clinical technologies.

One of the earliest and most comprehensive reviews of IS was coauthored in 1971 by a clinical engineering pioneer, Dr. Cesar Caceres. In a paper in the *Annual Review of Information Science and Technology* (ARIST), Dr. Caceres identified many of the emerging roles that early IS played, including clinical information management, medical diagnostic support, and general administrative and financial services. Although he enthusiastically predicted a valuable role for IS in health care, his mainframe-based viewpoint could scarcely have anticipated the rate of change that the modern microprocessor would facilitate. Despite the compelling importance of IS in medicine, that ARIST review has not been updated in more than three decades.

Dr. Caceres pointed the way towards the future role of IS in health care, to “implement things useful to the physician in practice and spend medical information dollars in the implementation of service systems for those practicing physicians currently taking care of the increasing patient load.” His concern was that the then 6% burden of health care on the GDP (now 14%) increased demands on physician diagnoses. He foresaw IS as providing an important solution to the problem. Though great strides have been taken in this direction, much remains to be done, since few of the available IS tools are easily integrated and many physicians still rely on paper records and personal diagnostic skills. In fact, most of the IS progress has occurred in three areas: Billing and administration, medical imaging, and clinical laboratory work. To date, however, even these applications have suffered from proprietary designs that limit electronic information sharing and integration.

This section examines the key technological elements needed to understand how IS produces dramatic diagnostic and therapeutic advances. The first chapter, Information Systems Management, is a tutorial on information systems. Information systems (IS) in health care have become a standard and fundamental infrastructure, as much as reliable electricity, clean water, and adequate heating, ventilation, and air conditioning. The IS role will continue to expand, spanning virtually all business and clinical care processes. The chapter is written for the clinical engineering manager, who must provide technology leadership in the health care institutions. The topics covered focus on crucial management issues rather than deeply technical topics in order to create a framework for the clinical engineer (CE) and biomedical engineering technician (BMET) to contribute to this growing field.

The next chapter, Physiological Monitoring and Clinical Information Systems (CIS), addresses both the technologies of bedside monitoring and CIS, and their interdependencies. The state of technology in both areas, reasons for the integration of the two, and the groundwork necessary to manage them are discussed. A brief overview of an electronic patient record (EPR) and the impact of physiological monitoring and clinical information systems have on EPR are presented.

The following chapter, Advanced Diagnostics and Artificial Intelligence, shows that the application of advanced diagnostics and artificial intelligence technology in the field service industry has yielded significant improvements, due to intelligent dispatch and the assignment of both parts and service engineers. The author examines both the current state of technology and experiences in the application of problem diagnostics and resolution technology in the health equipment field service industry and explores the successes and failures of artificial intelligence and the advanced remote diagnostics and decision-support methodology.

The next chapter, Real-Time Executive Dashboards and Virtual Instrumentation, shows how multidimensional executive dashboards can empower health care organizations to

make better and faster data-driven decisions by leveraging the power of virtual instrumentation and open architecture standards. Through case studies of bed management/census control, operational management, and data mining and business intelligence applications, the author shows how user-defined dashboards can connect to hospital information systems (e.g., ADT systems and patient monitoring networks) and use Statistical Process Control (SPC) to visualize information.

The chapter on Telemedicine: Clinical and Operational Issues reviews the evolution of this technology and the major issues to consider before initiating a telemedicine program. The authors draw upon their experiences at a leading medical center. Telemedicine is a relatively new modality in the health care delivery system, and many providers are still debating the appropriate entry course and the following regulatory and sustainability issues. This chapter provides guidance for those who are contemplating implementation of this technology.

The next chapter gives a detailed description of Picture Archiving and Communication Systems (PACS), systems that electronically process, store, distribute, and retrieve digital medical images in a portion of, or throughout, a health care enterprise. PACS epitomizes the integration of medical, computer, and communication technologies with its requirements for large amounts of storage, sophisticated databases, large-bandwidth, high-speed networks, computational power at the desktop, ease of use, for a variety of people, and specialized medical application software. The author notes how PACS can improve the imaging department workflow compared to film-based technologies and emphasizes that the practical implementation of PACS requires a high degree of integration with the Radiology Information System (RIS) and/or the Hospital Information System (HIS) for scheduling, workload management, and radiology reports. As PACS reduces film use, film processing, and film storage costs, as well as the number of lost films and retakes, it continues to develop, facilitated by the growth of high-bandwidth intranets.

Another chapter, The Changing Face of Wireless Medical Telemetry, provides a brief summary of electromagnetic interference (EMI) problems for the traditional wireless medical telemetry widely used in hospitals and provides information that clinical engineers can use to reduce the risks of EMI. The chapter describes the worrisome interaction between EMI and medical devices and what has been done to address these concerns. It highlights the creation of the new wireless medical telemetry standard (WMTS) and relates the need to make immediate assessments of medical telemetry equipment and plans to address the coming changes to the airways where wireless medical telemetry has been used.

The author of the HIPAA chapter penetrates the labyrinth of legislation and associated rules to show that clinical engineers must implement solutions to problems wrought by broad changes in health care technology. HIPAA's security rule was conceived to protect the integrity, availability, and confidentiality of health information or data associated with a patient. This includes the obvious; i.e., data in medical and billing records found in provider information systems, but it also includes diagnostic and therapeutic data found in biomedical devices and clinical information systems, a fact with broad implications for clinical engineering. Biomedical devices and systems used by health care providers represent a substantial and growing area of risk with respect to HIPAA security issues. The total quantity of biomedical devices and systems in a typical hospital may run 300% to 400% more than the number of IS-related devices and systems in that same hospital. The author reveals two major trends contributing to the significance of the biomedical technology-related risk. First, biomedical devices and systems are being designed and operated as special purpose computers with more automated features resulting in increasing amounts of health data being collected, analyzed, and stored in these devices. Second, there has been a rapidly growing integration and interconnection of disparate biomedical and information technology devices and systems where health information is exchanged.

The chapter on “Information Management Year 2000” (Y2K) describes the genesis, recognition, and remediation of the problem of computers using only two digits to designate a particular year, (e.g., using “17” to mean “1917”). Memory was precious in the early days of computing. During the 1980s and 1990s, medical devices incorporated computers and associated software. During the mid-1990s reports surfaced of an inherent and possibly fatal flaw in many of these devices. Computer experts predicted that many systems would produce unpredictable results and some might catastrophically fail as the

calendar passed from the year 1999 to the year 2000. Some experts postulated that these failures would occur because systems were incapable of recognizing that the year 2000 followed 1999. The author describes the benefits of the remediation efforts, completed at enormous expense. The author also provides a review of our reliance on technology and the vulnerability that represents, the recognition that the vulnerability of reliance on technology required contingency planning, the realization that the replacement of obsolete or unsupportable technologies was long overdue, and that recognition that more effective risk assessment and management methods needed to be developed.

The section concludes with the chapter *The Integration and Convergence of Medical and Information Technologies*, which describes the convergence of clinical and information

technologies in the face of two emerging trends the widespread use of commercial off-the-shelf (COTS) hardware and software, and communication technologies that interconnect the office, the enterprise, the community, and the world. COTS technology significantly reduces manufacturers' costs and improves manufacturers' time-to-market for new products. These technologies allow many of the major medical systems that are sold today to operate as computer systems as well as medical devices. The modern hospital can interconnect these medical devices using standard data ports in patient care areas and standard wiring, hubs, switches, and routers in data closets. These systems integrate information and clinical technology, and support of these systems requires an integrated approach by those who are trained and familiar with both clinical and computer technology.

Information Systems Management

Elliot B. Sloane

Assistant Professor, Department of Decision and Information Technology, Villanova University
Villanova, PA

In many ways, information systems (IS) in health care have become a standard and fundamental infrastructure essential, just like reliable electricity, clean water, and adequate HVAC. It is likely that the IS role will continue to expand, spanning virtually all business and clinical care processes. This chapter provides a framework for the clinical engineer (CE) and biomedical engineering technician (BMET) to use in managing their careers in the years ahead. Some CEs and BMETs attempted to distance themselves from the personal and business computer systems of the 1990s, citing their irrelevance to patient care. Fortunately, that is no longer a useful debate; most business and clinical systems now share most of the same common hardware and software components, regardless of the application. Today's IS situation has been shaped by three key factors: (1) the rapid price reductions for IS equipment and rapid increases in computing power; (2) hardware and software standardization and reliability; and (3) the stabilization of data communication standards. Today, many complex systems are developed using combinations or variants of commercial off-the-shelf (COTS) components, thus making it far easier to apply common system design, implementation, and support skills throughout the health care system.

The reader who seeks technical training will find many appropriate sources on the Internet and at bookstores, libraries, and community and engineering colleges. Therefore, this chapter is written instead for the clinical engineering manager, who must provide technology leadership in the health care institutions. The topics that follow focus on crucial management issues rather than deeply technical topics.

Convergence of Health Care's Business IS and Clinical Technologies

Because the cost of standardized microprocessors, sensors, memory, and wired and wireless data communication devices has dropped to just a few dollars per component, these elements are being used ubiquitously and pervasively throughout institutions. The time might not be far off when virtually every electrical and electromechanical device has the ability to capture, store, analyze, and communicate data to help enhance its performance and reliability and to allow it to contribute to overall system performance and reliability. The inherent value of this technology is its ability to configure and monitor the performance and safety of the device that it controls and the ability to communicate the device performance, problems, and relevant patient data throughout the institution's IS "nervous system." This ultimately can allow reliability by communicating problems earlier and more comprehensively and can afford more safety and redundancy by sharing computing resources when problems occur.

Operationally, health care institutions are finding that increasingly more departments, whether administrative, operational, or clinical, are able to interconnect or directly share full- or part-time IS resources like computers, memory/storage, communication pathways, and input/output devices. This has brought IS and biomedical technology support teams closer technically, but it also has sometimes created turf conflicts. Successful management of these converging and pervasive technologies requires that all parties collaborate to ensure that the clinical users and patients receive seamless, reliable support in the most efficient manner possible. To do so requires a long-term commitment to learn, master, and, ultimately, manage these technologies professionally. This chapter is intended to help make that possible by enabling clinical engineers and biomedical technicians to understand the IS field better.

The basic building blocks of IS infrastructure today might be captured in the areas of IS design and management methodologies, computing hardware and software, and data storage and communication. The following information about these areas will help clinical engineers and technicians to participate more effectively.

System Analysis, Design, and Management

The first topic that must be discussed is IS analysis, design, and management because the intended purpose and environment of use must, by necessity, define the hardware and software that will be used. Although most IS texts delve deeply into systems life cycle

methodologies for the new engineer or business student, this should not be a new area for health care technologists. Health technology assessment and life cycle cost-analysis techniques now include the use of flexible, computerized decision-support-system tools. The reader must assume that virtually all IS projects require several careful analysis phases to understand the feasibility and consequences of an IS decision. It is likely that the health care system will need to live with each installed IS for many years to come, and the overall systemic expenses, reliability, and efficiency of the institution is likely to be significantly impacted by each IS as well. The key areas of concern for health care IS system designs are not dissimilar to those for any medical technology. The selected system (1) must be evaluated using an accurate set of specifications that describe the necessary features and their relative priority; (2) must be properly configured to integrate efficiently and reliably with current and future IS systems in the institution; (3) must be installed and tested for proper function according to a written specification, prior to acceptance; and (4) must be included in the institution's ongoing technology management program to ensure reliable testing, maintenance, and repairs.

Needs Analysis

Competent IS specification and evaluation is by no means a simple task today, nor is it likely to become easy in the near future. In the absence of explicit FDA standards for medical devices, medical software, or human factors, most vendors have pursued their own, often unique, designs. In every health care market niche, therefore, the available IS choices vary widely in features, total cost of ownership, and overall compatibility. *Caveat emptor* ("Let the buyer beware"), therefore, must be the institution's policy. This must start with a careful analysis of the actual need to be fulfilled by the system and, importantly, the other systems with which it should successfully interface. Even if an institution or user believes that interfacing is not essential, one should be wary of giving up this option. Too often, the need to expand the system and/or to integrate it into a larger mission will emerge, and the cost for custom interfacing at that point can be enormous. One must be certain that the system can be efficiently and effectively learned and used by the intended staff, as well. Despite many decades of research in the human factors area, too many IS developers fail to take the time to understand the people, skills, and environment in health care. Poorly designed IS designs can cause major and unsolvable training problems that lead to unsustainable error rates and/or abandonment because using them "feels worse" than doing without.

Total Cost of Ownership

Careful system evaluation must take total cost of ownership (TCO) into account (see Chapter 30). Many other industries have come to respect the hidden costs as much as, or more than, the obvious purchase costs. In doing a TCO analysis for an IS project, one would be well advised to consider the consequences of successful adoption and growth on the need for additional hardware, software, and support in the three- to five-year period ahead. It is interesting to see how many IS analyses fail to plan for success, even though that is the hoped-for result of the acquisition. In many cases, success will lead to more users, greater dependence on the system, longer hours of use, ever-increasing storage and retrieval demands, greater printout support, remote access and security, and, ultimately, integration with other IS resources in the hospital. Additional hardware and software capacity can be assessed and controlled more easily if the IS uses a significant amount of COTS hardware and software. The larger the non-COTS portion, the more uncertain the costs and risks will be. One must not exclude the inherent application software from this assessment, either; if it is not based on industry standard operating systems, languages, and data management software packages, the sole-source nature of the system can become an increasingly expensive and inconvenient limitation. If the happy outcome of the IS selection and implementation leads to successful use and adoption, one should plan carefully to ensure that the institution's budget will enable the IS to meet the dependability demands of the use. In health care, many successful systems rapidly become "business critical systems" on which many people and health care delivery processes are dependent. This usually requires improved electrical supply, temperature and humidity control, capacity, stability, backup and recovery resources, and increased data communication

capability. A TCO analysis that does not address these issues will grossly underestimate the budget required to support the IS project. There is rarely a “perfect” IS product to select; each introduces different, and sometimes complex, trade-offs. Again, *Caveat emptor* should be firmly in mind, as the vendor will rarely bring these issues to light in his own analysis. If the IS project is expensive and likely to become so successful that it will become part of the institution’s infrastructure for quite a while, it may pay to use a decision support system like the Analytic Hierarchy Process (Schmoldt et al., 2001) to help document and weigh the pros and cons.

System Installation and Acceptance

System installation and acceptance testing is becoming more and more complex in today’s hospital, especially because many IS products must share electrical and data communication infrastructure; in fact, some systems share much more, including terminals, printers, and data storage. Purchasing documents from the institution should specify the vendor’s provision of specific acceptance testing methods, ensuring that required interfaces with other existing or planned IS resources are fully detailed. If these details are omitted, finger-pointing is inevitable, and the ultimate satisfaction of the user and the successful on-budget installation can be seriously jeopardized. In this rapidly evolving field, few standards are fully complete, and even fewer vendors are totally compliant with all aspects of the standards that do exist. The best of the IS standards in health care often have gaps, if for no other reason than the field of medicine and the business of health care are rapidly changing. Most standards take years to be written, and by the time they are published and adopted, new major changes in the environment, such as outpatient care, robotic surgery, telemedicine, or hybrid drug/device combinations, have been adopted. If the new IS cannot adapt to the existing or planned system, or if changes to the existing or planned systems are required, then the TCO analysis might need to project significant extra costs to show that impact accurately.

Maintenance

The ongoing management of the new IS project is likely to require a combination of user, in-house engineers and technicians, and outsourced maintenance and repair support. Some responsibilities, such as changing paper, printer toner and ink cartridges; recalibrating printers, charging batteries; and maintaining backups may fall to the users or their department. Even if they do, the costs of training and retraining staff and the necessary supplies belong in an accurate TCO analysis. Some institutions create or subcontract for “help desk” (see Chapter 99) services to assist the users; if so, the pro-rata costs for the new IS project can be allocated. Although complex preventive maintenance is rarely needed for IS technologies, it is wise to allocate some resources for regular vacuuming of dust, cleaning of filters, replacing crucial batteries, and managing and optimizing disk-storage space as required by the system. Another often overlooked, but crucial, maintenance task is the creation of backup disks or tapes and routine periodic testing to ensure that those backups are actually usable. Ensuring usability can be much more complex and time consuming than initially expected because proper testing may require access to a complete, identical system! Otherwise, the testing may be of little use if the original system has a catastrophic failure. The backup copies can be useless if they cannot be read by a different system or if there is no way to locate or to assemble an acceptable replacement system rapidly.

Maintenance and repair have long been in the domain of the CE and BMET. The passage of the Health Insurance Portability and Accountability Act (HIPAA) (see Chapter 104) has led to increased CE and BMET responsibility because many devices that they maintain hold or communicate patient-specific medical information as a consequence of the pervasive deployment of microprocessor technologies to such devices. In brief, practices and policies need to be created to ensure that patient-specific data are erased before any device is released for outside service and that memory is electrically erased or physically destroyed before it is disposed of or sent out for repair. For further guidance on this topic, contact the American College of Clinical Engineering (ACCE) at its web site, ACCEnet.org; The ACCE HIPAA Taskforce is currently developing a device-by-device HIPAA risk profile to make it easier to identify affected devices. (See Chapter 130.) If in doubt, however, it is probably wiser to err on the side of caution and to take extra precautions to erase patient data whenever possible.

A further maintenance and repair concern is that all devices, software, and communication systems might not be precisely compatible even when industry standards allegedly have been met. This can be a serious problem with software-configurable devices and systems because a small defect, incompatibility, inadvertent misconfiguration, or other inconsistency could be extremely difficult to detect. For example, a display monitor that looks identical to others but is defective or set for lower resolution or contrast could be difficult to detect, but it could cause disastrous diagnostic or therapeutic mistakes by eliminating clinically significant details. Further, a device could cause other systemic failures throughout the IS when it is connected through the network by tying. For example, a device that causes extensive resending or reformatting of digitized data throughout the IS could “tie up” limited bandwidth, memory, and/or computing resources, causing other parts of the system to slow down or malfunction. The only way to prevent such problems is to develop, document, and enforce careful device and system validation at the time of maintenance or repairs. If the hospital’s overall IS is a complex mixture of technologies from diverse manufacturers spanning many generations of technology, such validation could be onerous and expensive, thus affecting the TCO.

Privacy and Security

Two additional critical health care IS management topics that need consideration are privacy and security as legally mandated by HIPAA regulations. Virtually every health care institution is legally required to ensure that only individuals who have a genuine need or right to know a patient’s medical information can have access to it. Because much of the information is now in electronic form, software and hardware must be used to reliably prevent unauthorized access. Not only are passwords needed, but mandatory password-

update cycles and documented training to prevent sharing passwords or private information are also needed. To enforce compliance and to rigidly restrict access to confidential information or sensitive systems such as drug prescriptions, institutions also may selectively implement biometric screening (e.g., iris, fingerprint, voice, or facial scanning) and/or personal physical access control devices (e.g., smart cards, magnetic cards, IR tags, or digitally encoded buttons). However, these security measures are only effective if access to each terminal, printer, communication port, and removable disk drive is physically restricted to authorized personnel and for the intended duration of their use.

The aspect of privacy that relates to restricting IS access moves the discussion to one important facet of security ensuring that unauthorized individuals cannot access the IS. Not only is physical protection needed for IS resources within the institution, but it also is needed to prevent potential access by outsiders. The most serious outside risks are via the communications channels to the IS, including unauthorized tapping into wired or wireless networks and Internet and telephone/modem connections. The last two generally can be addressed by a combination of robust hardware and software firewalls, but addressing the network issues can be difficult indeed. At issue are the trade-offs between convenient and inexpensive access and reconfiguration of wired and wireless network stations and the need for security. The penalties of violating the HIPAA law might leave little alternative but to embrace cost and complexity of formal network restrictions, but it probably will take time and audits, to ensure that the necessary steps are not quickly abandoned or forgotten. “Locking down” the network most likely will require investment in encryption technologies and putting network access and control authority in a few key support staff’s hands, which could affect the TCO analysis. Ensuring that these individuals are available whenever required, and providing adequate software and hardware for them to use could become a far more visible cost to health care institutions. Two remaining aspects of security bear further mention. They both relate to ensuring the integrity of the patient’s medical data, because the data could impact diagnosis and/or treatment directly. Essentially, the burden is on the institution to ensure that every patient’s medical data is protected from inadvertent or unseen damage, change, or partial or total loss. The means for doing this are not simple, requiring a judicious mix of hardware, software, and procedures for compliance. Physical system protection, data backups, and disaster-recovery practices, as discussed above, are parts of the solution. In addition, special hardware and software reliability enhancements for the system, as described in the system and communication sections below, could be needed.

IS System Components

The key components of an IS were classically defined by Von Neumann as input/output, memory, and a logic/computational capability. When these three elements are combined, they perform computing tasks by following carefully orchestrated sequences of instructions that represented in programs provided by human developers. Practically speaking, input/output can be broadened to include physical devices (e.g., keyboards, printers, and displays), biologic sensors (e.g., ECG, blood pressure, and pulse oximetry), of all sorts, and communication technologies that move data from place to place. The memory elements can be static (programmable or erasable memory PROM or EPROM), dynamic random access memory (RAM) that may be in the form of separate chips or imbedded within a microprocessor’s own packaging, or disk drives of many forms, including CD/DVD optical storage and magnetic floppy or rigid disk drives. The logical/computational capability can be in the form of general purpose microprocessors of widely varying cost and speed or specialized, low-cost, dedicated logic devices with limited roles.

Before discussing these elements in further depth, it is critical to realize that the low cost and miniaturization of electronic components has resulted in many, if not most, products having built-in input/output, memory, and logic/computational that allows it to perform its task more reliably and flexibly. It is unwise, therefore, to oversimplify the complexity of current and future computing technologies because, in fact, they are made up of multiple interconnected computing systems. Successful design, implementation, and repair of such systems require understanding the role of each component as well as its function within the larger system.

As more and more health care technology shifts to multiple interconnected digital platforms (digital convergence), the design, installation, and support challenges expand. Not only must each device perform as designed, but the entire systemic performance must be validated every time a change occurs. Unfortunately, such changes might be invisible, in the form of program changes (e.g., patches and updates) that might not even be documented or detectable. Emerging standards in the health care field may in the management of these problems, but the multivendor, multigenerational interconnection of technologies required in most institutions will keep a significant portion of the burden on its own staff, not on the manufacturers or government agencies.

Input/Output Technologies

The input/output technologies in health care applications play an important and often overlooked role, as they may inadvertently damage the human information that they are used to represent. This problem is a byproduct of the necessary conversion of analog signals that characterize life and the discrete, or digital, nature of the IS components. The human analog signals must be converted from analog to digital (A/D) before they can be managed by the IS, and then must often be converted to another analog representation such as a display monitor or printout, which requires some form of digital-to-analog (D/A) conversion. Although the frequency and rate of change of most human waveforms is quite slow, relative to many other areas of technology (e.g., radio and radar), the fidelity of A/D and D/A processes is a function of providing enough speed, resolution, and faithful storage and computing to ensure that critically important diagnostic or therapeutic details are not lost or distorted. The ECG signal provides a simple example: If A/D conversion is performed either too slowly or with too little resolution, the digital data

obtained and used for diagnostic or therapeutic interventions can be forever damaged by losing fine details, right from the outset. Further, even if the A/D process is correct, if any part of the storage, communication, or computing systems that handle the digital data fail to maintain or interpret every bit in the digital representation accurately, permanent loss of information and/or inaccurate analysis and intervention may occur. Finally, even if the digital representation is accurate within the system, inadequate D/A conversion into a graphical image on a display or printer can prevent a clinician from seeing critically important details.

Problems from this later D/A stage can be very difficult to avoid, as they often also depend on the human observer's optical, auditory, or tactile interpretation of the analog representation. The cognitive abilities and limitations of the human-computer output interface are still being studied, but it is clear that there can be wide performance variations of human and technology that greatly affect the result. Using the ECG as an example, a statistically significant number of clinicians might not perceive certain artifacts on a display, due to their inability to accommodate the contrast or intensity limitations—or settings—of that device. A simple systemic failure like this can be difficult to isolate and repair today, as many clinicians might use different displays, both portable and fixed, and both local and remote, during the course of a day.

The above examples are cautions that the clinical engineer and biomedical electronics technician should bear in mind whenever they work with I/O devices. Even though most of these devices might be very simple and reliable by themselves, when integrated into a health care system the overall safety, reliability, and performance of the system might be severely but unobtrusively limited by the weakest link's failings. Another new risk is that many medical devices could become input devices to other processes that were never considered in their initial designs. The data port from an infusion pump could become the data source for another manufacturer's drug interaction warning system or patient record charting system. Newly discovered drugs, novel dose dilutions, or unexpected use of stand-alone pumps without data ports could defeat the expected safety, clinical, or administrative role of the system.

Aside from the systemic issues mentioned above, certain aspects of digital I/O bear cautious consideration as well. We know from classical clinical, electrical, and mechanical engineering experience that analog waveforms often must be amplified and filtered carefully to ensure reliable fidelity. Many of those techniques now have been subsumed by digital signal processors (DSPs), which can provide inexpensive and flexible waveform manipulation using computation rather than capacitors or inductors. The DSP allows complex filter designs that would be difficult, expensive, and perhaps even impossible, with physical components. These products have allowed signal retrieval and enhancement in situations never before possible. At the same time, there is no simple way to anticipate or control the interactions that can occur when multiple devices are interconnected in a system. The ideal outcome is to achieve a cumulative advantage for the system, but that should not be taken for granted. An unexpected induced artifact (e.g., a newly enhanced signal that is larger than expected, or the removal of part of a signal by a filter that was inadvertently turned on) could cause disruptions or serious adverse consequences. The DSP is likely to be more widely deployed for many purposes and should not be ignored in design, installation, or maintenance.

Communications

Telecommunications, digital communications, and networking might be considered a separate field in many texts, but they are included here to suggest to the reader that they could, and should, be viewed as a continuum, extending the distance and/or flexibility of I/O among patients, doctors, devices, and IS components.

Telecommunications

Telemedicine and telehealth are discussed elsewhere in this handbook (see Chapter 101), but their growing deployment offers further support to this chapter's approach. When needed, physicians can remotely download ECGs, reprogram pacemakers, order prescriptions, and share diagnostic X-rays, and it seems that more and more medical care can be, and will be, delivered this way. A decade ago, the clinical engineer might have comfortably ignored telecommunications as "merely" supporting discussions or business faxes that would be like sticking one's head in the sand today. Traditional telecommunications systems used relays and digital switches to create wire-to-wire connections for analog signals (i.e., sounds). Modern telecommunication systems, however, often convert sound to digital data, using D/A and A/D devices like those mentioned above. Even if a standard telephone handset is used for a person-to-person conversation, there is little or no way to know whether digitization is occurring at one or more points along the route. Many medical devices can use telephone connections to share data, and wired or digital telecommunication technologies each can introduce unique distortions that can be difficult to detect, diagnose, or fix. If one is to be responsible for ensuring reliable medical communication via phone lines, one must understand the telecommunications technologies that are available. With that knowledge, there is little to separate the training and ability that are needed to support regular business and personal phone calls.

Facsimile transmissions (faxes) use a combination of digital and analog techniques to transfer images from one point to another, typically via the telecommunication system, although the Internet is sometimes used instead. With the emergence of HIPAA security and privacy laws, the simple FAX machine is being called into service—perhaps as an interim fix—to send patient information to other doctors or institutions without using formal digital pathways like e-mail or web servers. Technically, this might be seen as a step backward, but it sidesteps some of the more rigid rules, and risks, in the HIPAA law. Specifically, HIPAA's regulations excuse discussions or documents being sent by telephone, as they are not stored, nor intentionally transmitted, in digitized electronic form. One presumption of a telephone or FAX communication is that it is a point-to-point connection of wires, in which the recipient's phone number ends at a known location like a doctor's office or a patient's home. Electronic transmission by e-mail or digital document

on the Internet is not exempted from HIPAA regulations, however, as those documents must go through many public and private computers en route to their destination. Unless the documents are encrypted in a secure fashion so that only the intended recipient may view them, they may be read by one or more unauthorized parties, violating the patient's privacy. The result is that many physicians have been advised not to communicate by e-mail or web sites, leaving the FAX as one of the few convenient alternatives. Unfortunately, FAX transmissions suffer from numerous limitations, including crude scanning and printing resolution for most inexpensive products, and unpredictable handling of colors. As described in the above ECG example, this may cause unanticipated artifacts and distortions in the received record, and the problem will be exacerbated by repeated faxing from one physician to the next. This issue is only now emerging, and it might take some time before these problems are well documented and understood. Suffice it to say that this is another example of a technology that could affect the quality of medical care, putting it well within the purview of most clinical engineers and biomedical technicians. As an aside, the HIPAA exemptions to using FAX may be short-lived, because today there is not really any way to prevent the FAX from being routed through a digital or Internet network anyway. Many available telephone systems use digital routes and techniques to save money and time. Unless the user can ensure that both the sender and receiver are truly connected to analog phone wiring, HIPAA constraints may continue to reign.

Digital Communications

We now can shift to a somewhat more technical discussion of general digital communications, networks, and the Internet, to provide a working vocabulary and understanding of the basic principles that will be helpful in the field. There have been many communication and network technologies over the past couple of decades but increasingly more companies are using a limited number of industry-proven standards, which makes the discussion a bit easier. We will begin with wired communication technologies and will close with wireless ones.

Digital communication generally requires reliably sending and receiving binary (1/0, or on/off) signals, which may be represented by a pre-agreed combination of (low) voltage, ground, or a (low) negative voltage. Any two devices could be designed to share digital data as long as they shared a pre-agreed protocol, such as "on" or "1" being 5 volts and "off" or "0" being -5 volts. The other element needed for reliable communication is a timing protocol to ensure that the recipient is measuring the signal at the right time. To accomplish this, either synchronous clocking signals are sent in parallel, or asynchronous triggers (timing signals) are embedded within the data stream. With synchronous communication, an extra wire or pair of wires sends a clock signal. Because the clock and data signals would encounter similar distortion along the route, a clean clock signal might serve as a validation that the wiring path is adequate. Each time a clock pulse is detected, the voltage received can be measured, determining the on or off state of that bit. Asynchronous communication depends on both the sending and receiving device having an extremely reliable and precise crystal timing clock working at formally agreed rates. The receiving device waits for an initial signal to tell it that the message is starting, and then uses its internal clock to pace its measurement rate. Depending on the agreed-upon protocol, the message will usually last a fixed number of time intervals, or the message will begin with a numeric value telling the message length before the data itself is sent. Extremely large amounts of data may benefit from sending multiple signals on separate wires simultaneously, which is called "parallel communication." A common multiple is 8 bits, or signal wires. When configured with an electrical ground wire for each clock wire and a clock and ground wire, each such cable will require at least 18 wires plus spares and any external electrical shielding. Because the cost and size of parallel cables is significant, they are used only infrequently, such as for connecting some printers and for high-speed computer connections (e.g., SCSI). Most current communication systems use an asynchronous serial-information format instead of clocked parallel signals, sending one signal after the next using careful timing to separate them. RS232/422, Ethernet, USB, USB-2, and Firewire formats are based on asynchronous serial communication.

Even if all voltage and timing agreements are in place, proper electrical and mechanical designs are needed to ensure that the voltage and signal shape are not degraded (i.e., diminished, delayed, or otherwise harmed) along the way. Even the best designed communication system designs, it is difficult to guarantee that some external electrical, mechanical, or other problem has not adversely influenced the communication. Therefore, most designs include an active exchange of confirmations between the sending and receiving devices to ensure that the intended message got through accurately. Simple communication software within the devices handles this automatically.

The software generally requires that the sending device describe the length of the information being sent as well as one or more quality control parameters. For example, the sending message might inform the recipient that it should receive 256 signals and that, when added up, there should be an odd or even quantity of 1s in the message, called "even or odd parity." This simple format will serve well if a single bit is lost, but it is not adequate for critical data because interference that causes multiples of an even number of 1s to be misinterpreted as zeros still would have the correct parity. For most high-speed communication, therefore, more sophisticated coding systems are used. These systems work by performing more computations on the data being sent, and then sending data about characteristics of the message that should be received at the end. If the recipient's device performs the same computations on the received data and finds that it does not match those sent with the message, it knows that a problem exists. In some cases, the receiving device is given enough information to repair simple mistakes, but a simpler handshaking communication protocol is often used instead.

If the receiving device is satisfied with the quality and accuracy of the message, it can send its own brief confirmation message, "ACK," to the sending device; if the message was damaged, it can send a negative message instead, "NAK." The handshake protocol then may provide for a sequence of remedial steps to resend and recheck the message, including, if necessary, automatically choosing a slower transmission rate or even a different communication channel. In early RS232 signal designs, separate wires were

reserved for sending these handshake signals back and forth (“hardware handshake”), but modern designs provide bidirectional data and signal pairs and use coded messages for the same purpose (“software handshake”).

The software handshake protocol allows additional message and codes to flow between sender and receiver like a “busy” signal when a printer’s buffer is full, or a “toner empty” message when appropriate; these signals may be different for different systems, thus causing additional incompatibilities. For example, older Hewlett-Packard (HP) printers did not use the same codes as other printers did, which created printout problems. This is part of the reason why unique “drivers” or software programs are needed with different printers, scanners, and terminals so that the system can interpret the codes that it receives and take proper action. Today, inexpensive communication chips (UARTs and USARTS) handle much of the timing and handshaking automatically, leaving the higher-level decisions—like setting off an alarm when a color-ink cartridge runs dry—to device software to notify the operator to correct the problem.

Networks

Networks and the Internet generally rely on the asynchronous, software handshake protocols described above but add a few more formalities to the process. Ethernet, for example, has become a ubiquitous asynchronous network protocol widely used throughout hospitals. The nature of a network, however, requires that many devices are able to share the digital signal capacity of a single set of wires that run throughout a building. This minimizes the cost of sending the signals throughout the building but requires that the devices have a way to discern the messages that belong to it, and those it should ignore. To accomplish this, a combination of hardware and software is required.

A great deal of specific detailed networking information is available in textbooks and online sources like www.cisco.com, so only a brief overview is provided here. At the software level, one fundamental network design concept is that data are sent in finite length packets of bits with a digital address for the recipient at the beginning of the packet. Regardless of the network details, one basic networking rule is that all other devices should ignore messages that are not addressed to them. However, this does not mean that other devices cannot detect and read the messages, which creates significant security and privacy challenges in the health care setting. Every computer on the network has an internal network adapter card (Network Interface Card (NIC)) that handles the electrical design and communication protocols (Network Access Method (NAM) for the network it connects to. That card also has a unique ID number, known as the “MAC address” (network Method Access Control).

Topologies

Three general cabling layouts, known as “topologies,” can be used: The star, token ring, and bus. Each represents a tradeoff of wiring cost and communication speed and reliability. The star configuration uses a separate wire to each device, which offers high reliability and large signal width, but also has a high cost because wires must be run to every device in a building. A bus network can use one wire running all through a building, and each device can connect to the wire as it passes nearby. If the bus wire is broken, however, no messages can pass the break. Furthermore, if all of the devices sharing the bus are trying to send a lot of critical data, there can be many “collisions,” in which packets interfere with each other. Although the bus topology can be quite inexpensive, it can be readily overloaded. Without special software and hardware design and components, a simple bus network could prove inadequate for critical applications.

The third method, token ring, uses a continuous wire that runs all through the building and returns to the starting point. Messages spaces, called “tokens,” are time-allocated on the wire, and any device can put information into an unused token space with the MAC address of the recipient. As the tokens go past each device connected to the ring, the device reads the contents and makes a decision: If the token is addressed to it, the device reads the contents and either stores its own message to send or clears the token for other devices to use. A token that goes all the way around the ring without being read is erased because the recipient device is assumed to be offline, and the sending device is free to take other corrective action as needed. The token ring has another advantage in that if the ring is broken at any point, the signals still can propagate to all devices.

In actuality, no single topology is universally or exclusively preferred. In most institutions, combinations of all three are common, balancing costs, performance, and reliability as appropriate. Each subnetwork is connected to nearby subnetworks with a gateway that transforms the data signals and protocols as needed. The gateways work with a Network System Management system (e.g., Novell Netware™) to keep track of the location of each device by storing its MAC address and the subnetwork where it is connected. Messages are routed through the appropriate gateways until the desired subnetwork is accessed. When the collection of subnetworks is located in a single building or area of a building, it is usually called a “Local Area Network” (LAN). Larger networks that span multiple buildings on a manufacturing, research, or manufacturing campus are referred to as “Wide Area Networks” (WANs), and city-wide networks are referred to as “Metropolitan Area Networks” (MANs). The longer the distance, and the higher the necessary total bandwidth, the more likely it will be that network wires will be replaced or supplemented with more expensive microwave or optical fiber links. Specialized NICs and gateways are needed to accommodate these enhancements, but the general architecture described above applies, regardless of the medium or the size of the network.

Internet

The Internet is a specialized network that was designed by the Department of Defense’s Defense Advanced Research Projects Agency (DARPA) as a reliable global network that can withstand major physical damage without stopping messages from being received. The Internet functions in a similar way to the general networks described above, with two major exceptions. First, each device on the Internet has an Internet Protocol (IP) address that is quite different from LAN/WAN/MAN MAC addresses.

An IP address is a four-part number, known as a “dotted quad” number. A dotted quad number comprises four separate numbers that are divided by a decimal point (e.g., 174.201.33.101). Each unique number functions like a MAC address or a phone number; the dotted quad IP address represents the address for that particular device or user. Some numbers are permanently assigned to a device, such as a company’s main web server. Other numbers are dynamic IP addresses, assigned to individual PCs or devices as soon as they connect to the Internet. The IP addresses are maintained in an international collection of Domain Name Server (DNS) computers connected to the Internet for the purpose of keeping several pieces of Internet addressing information in global sync: Each valid IP address, the textual name assigned to that address (such as www.att.com), and the physical location of the device with respect to its nearest access point to the Internet network.

The global matrix of web sites connected by the Internet is known as the “World Wide Web” (hence, the “www” prefix on most web addresses). Information that is sent via the Internet is broken into packets, each of which has an IP address for the sending and receiving device, sequencing information for each packet, and the time it was sent. Each packet is sent to the nearest Internet access point and it is then read by the nearest Internet packet-forwarding station. These stations are run by military, government, academic, and commercial institutions, based on international contracts and agreements.

The packet forwarding stations get DNS information for the recipient and make a decision to send the packet to another nearby forwarding station. If the forwarding stations or communication lines in the general direction in which the message must go are busy, the packet will be sent in another direction. Each forwarding station moves the packet in the best path it can calculate, with the ultimate goal being the delivery of the packet even if it has to go backward via a long journey around the world to its destination. The receiving device must wait until all of the packets expected in the message reach it, and then they are placed in proper sequence. If the message is satisfactory, it can send a message back to the sender confirming the receipt. If there is a flaw, or if one or more packets are missing, after a predetermined wait the receiver will send a request to the sender to resend the necessary information. If that request fails, the receiving device must presume that the sender is no longer working and notifies the recipient that the communication link has failed. In addition, if a packet-forwarding station finds that a packet has been moving around for a long time without making its way to the recipient, it can kill the packet so that further Internet resources are not wasted. This approach has proven very robust and reliable, which is one reason why the Internet has been so successful.

The successful system for forwarding stations used by the Internet is also its main Achilles heel for privacy and security, however. Every one of the forwarding stations can read, store, and/or possibly change the packets that it forwards. Unless each packet is encrypted in a way that prevents all but the sender and receiver from reading or changing it, the information is essentially open to the public. In addition, many government agencies around the world are believed to be scanning the packets for terrorist or other illegal content. The U.S. government, in particular, has required that the keys to any commercial encryption package be given to it, so even encrypted information could be visible to our government. This means that unencrypted, patient-specific health information, including files, e-mail, pictures, videos, and lab results cannot pass the HIPAA privacy and security rules. Furthermore, it would seem that sending FAX documents through the Internet would not be acceptable either, because they are not encrypted and can be printed easily with FAX-viewing software. These HIPAA conflicts are the reason why many doctors are limiting their patient-specific information to regular FAX, telephone, and/or regular mail. There may be ways around this eventually, including encrypted e-mail or Virtual Private Networks (VPNs), which use encryption and password controls to control the access to web sites and the privacy of information being sent through the Internet. While VPNs are not necessarily complex, they add new expenses because such services are run by private companies that charge for this capability.

Another emerging use of IP addressing is the so-called Voice over Internet Protocol (VoIP) telephony. This is an interesting technology because it uses the free and reliable worldwide bandwidth of the Internet for voice communication. This is essentially one specialized type of digitized voice communication that certain companies like Cisco Systems are championing. Within an institution, a VoIP telephone network may offer flexible installation and movement of telephones and may allow microphone-equipped PCs to serve as telephones as well. Investment in a VoIP system in a hospital may also reduce some wiring costs and complexities by eliminating some or all telephone wiring. After all, if digital wiring is going to be installed everywhere, why not consider using it for the telephone needs, too? Such installations still may need separate wiring for LAN applications, but the choice of VoIP wiring may facilitate deployment of wireless products as well.

VoIP allows routing long distance calls through VoIP services, thus reducing long distance calls to the service charges paid to local phone companies and eliminating commercial long distance costs. VoIP has limitations for long distance calls, however. When used within a facility, the VoIP signals may rarely overtax the bandwidth available. Once the digitized voice packets are sent through the Internet, however, uncontrollable delays may occur for each packet. The result might be choppy sound quality, which might not be an acceptable trade-off. If both parties on both ends of the communications have VoIP systems, however, special software and hardware can minimize these problems. Therefore, VoIP might be better suited for regional or national health systems, which can use long distance savings to help offset the cost of installing compatible VoIP systems.

Many network-based computers are also used to access the Internet. This access is facilitated by a special type of network gateway product that has the ability to maintain lists of the active MAC and IP addresses in use. All inbound or outbound IP addresses are routed to or from the correct MAC address by the gateway and the Network Management System (NMS). In most cases, each PC is assigned a dynamic IP address when it first connects to the Internet, conserving the available Internet connections for active users. By contrast, web servers that need to be constantly online would be assigned a static IP address so that the DNS system can properly route inbound requests for service.

Wireless Communication

Wireless communication (see Chapter 103) is becoming more and more standardized, and it often simply becomes an extension of the wired network. The most common protocols for achieving this are the IEEE 802.11 series. The 802.11a protocol is the oldest and slowest; 802.11b allows more bandwidth, and 802.11g is the newest, fastest, and most generally flexibly compatible of the protocols. Depending on the sophistication of the 802.11 components, partial or complete compatibility may be possible between each of these series. From the computer and network's point of view, each computer on a wireless link is addressed just as if it had wires running to it.

This 802.11 standard is offering new connectivity opportunities never before possible. For example, thousands of Starbucks Coffee shops are set up with 802.11 networks. Customers who pay for access can go online through the Internet whenever they are within radio range of a Starbucks, anywhere in the country. Special security challenges exist, however, because suitably equipped receivers can copy all of this wireless data. If adequate encryption software is not used during all confidential communications, anyone can see it. This presents a serious exposure for web sites and e-mail users, as userids (user identifications), passwords, and private information all could be exposed. Further, if the userids and passwords allow access to internal institutional e-mail, databases, and files, the public disclosure can open the institution to intrusion, hacking attacks, and other serious ongoing security breaches. Unfortunately, although most laptop, desktop, and tablet PCs have adequate encryption capabilities, many PDAs (e.g., simple Palm Pilots™ and HandSpring™ units) do not, thus making enforcement and control very difficult, if not impossible. The convenient, portable, reliable, and low-cost advantages of wireless 802.11 technologies for health care cannot be ignored, but each use may require careful planning and encryption controls to ensure HIPAA compliance.

Other wireless technologies are in use, and each has advantages and disadvantages. One, infrared (IR) communication, often used with PDAs and some notebooks, has the advantage of low cost and a limited amount of line-of-sight security control. Unfortunately, encryption is rarely used, limiting IR applications in health care to non-confidential data. Another technology of note is known as "Bluetooth," which is a low-power, limited-proximity radio link that should also be low-cost. Few Bluetooth applications are available as yet, but eventually the technology might allow physical docking areas where doctors, nurses, or family might access select network or Internet resources without creating radio interference for other nearby devices. Again, encryption of such messages might be limited or nonexistent, so HIPAA-regulated information might not be suitable for Bluetooth applications.

A third digital, in-house, wireless technique that is worth mentioning is the Internet's IP addressing scheme. As long as a radio frequency that complies with hospital frequency allocations is selected, some devices may use a wireless form of the IP address instead of a LAN. The fundamental difference is that the devices do not use a LAN MAC address but the four part "dotted quad" address mentioned earlier. The advantage of this method is that the devices can use standard web-enabled tools such as browsers or file transfer programs. In addition, installation of wireless IP capability can facilitate VoIP applications. This may ultimately allow safe wireless intra- and extra-facility telephone calls throughout the hospital, as long as the VoIP limitations mentioned earlier are not a major hindrance.

Privacy and Security Considerations

No discussion of communications in the health care world is complete without a few words about securing the communications to prevent unauthorized access or tampering. The rapid development of wired and wireless communication standards has made it far easier to train staff; acquire hardware and software; and install, test, operate, and test digital-based systems. This has not come without a price, however, in that the very same standardized components and software are available to anyone who wishes to tap into the system. This chapter cannot fully address this deeply technical and rapidly advancing field, but certain points should be made. First, the access to and from the Internet exposes the whole system to hacker attacks of many sorts. Viruses, for example, are readily attached to e-mails, files, and applications such as Instant Messenger (IM). An automatically enforced antivirus installation and updating methodology may be unavoidable. Unfortunately, the available programs are not free, and each one comes with trade-offs, like stealing significant computer speed from each user and causing occasional program

and hardware incompatibilities that can be severely disruptive. However, operating without such software cannot be easily rationalized.

Firewalls

Each Internet user is exposed to attacks through programs that can damage files, modify data, or steal confidential information because during their Internet session their IP address is visible to all sites that forward their packets. Malicious programs can use that IP address to send hidden instructions to the user's PC. For most facilities, therefore, a special suite of hardware and software firewalls must be installed to manage the traffic into and out of the facility. Firewalls are not autonomous products, however. They need to have updates systematically applied, and someone must evaluate the IP traffic to detect and counter a large number of potential threats. Although the threats are not solely external, those that are external require careful scrutiny to detect patterns of hackers trying to infiltrate or interfere with the firewall or other resources. The last thing a facility needs is for a hacker to steal disk, computing, or communication resources for some playful or malicious purpose. Some infiltrating programs have built-in time delays that allow them to hide silently once they have been installed.

Multiple isolated, brief intrusions can allow the institution's system to be attacked from within when staffing is low, thus creating significant internal or external damage. One external use is to create denial of service (DoS) or spam attacks on other outside computers. In a DoS attack, a large number of computers can be set up to simultaneously send bulky messages to, or request time and resource intensive services from, a targeted commercial or military site. Similarly, an e-mail spam attack may use one or more institution's email systems to send out thousands of pornographic, political, or advertising e-mails using its own lists and/or hospital e-mail lists. For this reason, some firewall managers often restrict the number of e-mail copies that any internal user may send and may set thresholds on the type, frequency, and quantity of Internet messages that any one user can send. Those limits can vary by day and time.

Further management of IP traffic is possible, including tracking or limiting e-mail use, scanning e-mail content for privacy and harassment violations, connections to child-pornography sites, and other violations of written institutional policies. Similar firewalls and strategies may need to be deployed within the LAN, WAN, or MAN systems to prevent or detect similar internal privacy or security violations.

Physical Access Controls

Physical access controls must be considered as well. Although the IP and MAC addressing schemes often can flexibly allow any user to plug any computer into any available wired outlet or wireless access point, that may not be supportable in most institutions. The alternatives include rigid password policies and enforcement and limited permission for key maintenance and technical support personnel to implement new or changed connections to the hospital's networks. The trade-offs are not simple. Allowing the networks to allow anyone with an Ethernet or 802.11 wireless adapter to access communication or computing resources might not be acceptable from a security and privacy perspective, but it does make it much easier for clerks, nurses, technicians, or even patients to install and move approved devices around the hospital. At the other extreme, restricting the control of such moves to a single person might not work either, as an emergency relocation of a patient and all of the associated network-based equipment to the ICU cannot be delayed because the person cannot be reached. Having available multiple persons on each shift could solve the problem, but clear documentation and communication will be needed in order to avoid problems.

Memory/Storage Technologies

Memory or, more generally, storage technologies present unique challenges and opportunities in health care. The good news is that storage technologies are becoming so inexpensive and reliable that most problems can be solved reasonably.

Physiologic Monitoring and Clinical Information Systems

Sunder Subramanian

Director, Clinical Information Systems, Information Technology Division, University Hospital and Medical Center, SUNY at Stony Brook
East Setauket, NY

The future direction of the clinical engineering profession will be tightly coupled with Information Technology (IT) more than ever before in the history of the profession. Convergence of the two professions is driven by factors such as advances in the state of the art in device technology, the need for integration of bedside data with clinical documentation, existing and emerging standards in the area of data communication, demand for accurate and reliable clinical indicator data by regulatory agencies, caregiver and customer knowledge and understanding of emerging clinical technologies, and consolidation of device manufacturers and clinical information systems vendors in the marketplace. This evolution is compelling the clinical engineering profession and hospital clinical engineering departments to expand their scope, knowledge, and expertise in the area of clinical information systems (CIS) and to become active participants in the selection, implementation, and support of bedside and clinical information systems.

This chapter addresses the technologies of bedside monitoring and CIS and their interdependencies. The state of the art in technology in both areas, reasons for the integration of the two technologies, and the necessary groundwork for managing these technologies are discussed. A brief overview of an electronic patient record (EPR) and the impact that physiological monitoring and clinical information systems have on EPR are presented.

Clinical Information Systems

One definition of a Clinical Information System (CIS) would be of a system that should interoperate with bedside monitors, bedside peripheral devices, and hospital information systems (HIS) in providing an integrated clinical information charting and data management support system in a local area network (LAN) configuration (Dyro and Poppers, 1988a,b). The capabilities of the clinical information system should be available to the user population distributed on this local area network in a multitiered health care enterprise that is part of an integrated health care delivery system. The CIS should be able to support user needs that are expected to be diverse and dynamic over the service life of the system with resultant growth and change in functional capabilities, data processing, and information-transfer volume (Gage et al., 1986).

The CIS should support generation of, and access to, clinical/patient information on a real-time and archival basis, with response times designed to eliminate manual charting burdens on the clinical staff. The architecture should provide a user-customizable, fault-tolerant redundant configuration for efficient and secure acquisition and entry, query processing, sharing and exchange, storage, and retrieval of clinical data. At the minimum level of functionality, the system should automate patient/clinical data acquisition, processing, storage, and retrieval and should provide capabilities analogous to existing capabilities with the elimination of the need for paper. The CIS should support real-time interfaces to bedside devices such as physiologic monitors and ventilators and to the HIS and ancillary systems such as laboratory, radiology, and pharmacy. This will reduce manual data entry and paper documentation by automating the flow of demographics and vital signs data, lab results, and medication orders into customized charts and forms. Clinical information presented this way is legible, recoverable, reproducible, and accessible throughout the enterprise. Providing integrated clinical information will assist caregivers in making informed clinical decisions about the care for their patients. An integrated query processor and a report writer are necessary to support datamining applications. These tools will greatly benefit quality assurance, regulatory compliance, financial, and research applications.

At the system level, the three critical requirements would be reliability, performance, and size. The best designed systems offer reliability through redundant fault-tolerant architectures where every component of the system is duplicated, thus eliminating or greatly decreasing the possibility of system failures that could result in loss of system availability and patient/clinical data. Response time, a criterion for measuring the performance of the system, is a function of the hardware and communication networks. High-speed processors, with large online storage, that are connected to clinical workstations using a fiber-optic network or high-bandwidth coaxial connections can sustain high data throughput and can provide fast response times. The size of the system, defined in terms of available system memory (RAM and hard drive), not only dictates the storage

capacity but also affects the retrieval speeds of stored data. A typical clinical information system that is necessary to store text, numerical, and graphical information will have large and high-speed storage subsystems.

CIS Architecture

Traditional systems such as radiology and pharmacy were best-of-breed application systems. These systems, due to their focus on the application, performed very poorly in the areas of data communication and integration. As a result, they became islands of clinical information, disconnected from the rest of the enterprise. In today's environment, it is important for a clinical information system to have the ability to communicate and seamlessly integrate with the rest of the enterprise. One such example of a CIS is the Centricity product from GE Medical Systems Information Technology (Centricity, 2002). Shown in Figure 98-1 is the architecture used by the Centricity Enterprise Clinical Information System product from GE Medical Systems.

Clinical information systems must incorporate industry standards on all aspects of their architecture, and this should apply across the board, from the user interface to operating systems and to clinical workstations. Using PCs as clinical workstations can be economical and user-friendly. A graphical user interface (GUI), supporting the use of a mouse or a track ball for most common transactions, would be necessary for the success of these systems. Using industry standard databases will enable clinical information systems to readily share data with other systems and to become a part of the enterprise's clinical information management solution. Industry standard communication protocols will enhance accessibility, security, and portability of clinical data over a distributed health care delivery system. A web-enabled CIS can provide caregivers access to clinical data over the world wide web using popular desktop browsers. In a distributed health care delivery system, with patients and caregivers separated by large distances in some cases, having e-mail messaging capabilities can be a useful clinical tool.

CIS Components

Components of a clinical information system include a powerful central computer system running the operating system and the application software with online and archival storage subsystems, communication/network, real time, and batch interfaces clinical workstations and bedside devices.

System Hardware

The Computer System

Clinical information systems typically use the client-server architecture with redundant processors and storage subsystems. In addition, the servers also have archival subsystems and communication links to other systems for sharing and exchanging information. System architecture will be optimized for central and distributed processing resources by partitioning processing capabilities to provide high-speed response times, while utilizing redundant, central data processing and datastorage architectures coupled with high-performance, intelligent clinical workstations. The architecture will also provide coordinated central and distributed processing functionality in data acquisition, processing, and retrieval, with response times optimized for transaction and information retrieval requests. In the event of a system failure, the clinical workstations will reconnect to the remaining functional system, and complete CIS capability will be available to the user with continuous access to all patient data. Most CIS configurations will support simultaneous running of training and production systems.

The state of the art in the server technology is to implement the application using the CITRIX server architecture (Citrix Systems). Hospital Information Systems departments, experiencing a decrease in their resources, face the daunting task of managing ever-increasing responsibilities. Heterogeneous computing environments further complicate the situation. The CITRIX approach enables the information systems departments to meet this challenge with streamlined installation and configuration, centralized administration, and security for

GE Centricity™ Enterprise Solutions

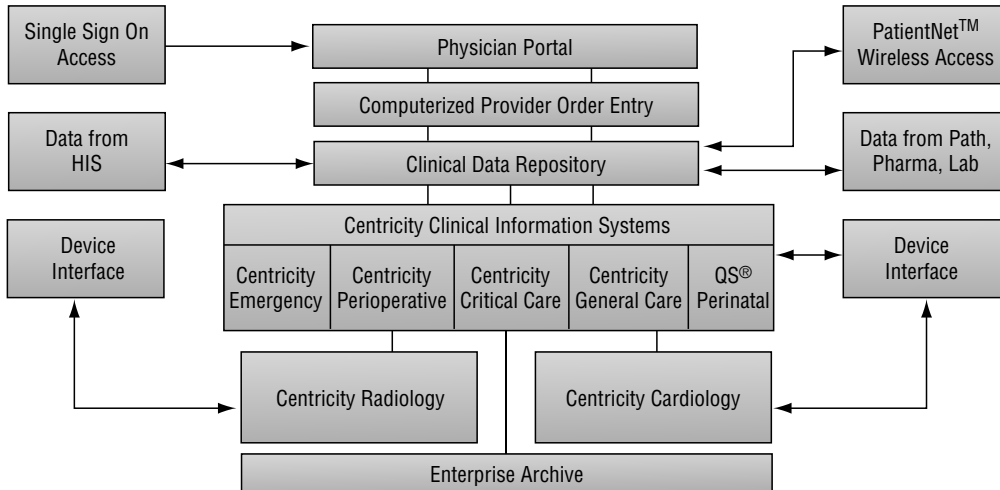

Figure 98-1 Centricity Enterprise Clinical Information System architecture from GE Medical Systems Information Technologies.

information and applications. Fast deployment capabilities and ease of management helps information systems departments to achieve rapid turn-out on upgrades and maintenance. In today's market, some application vendors certify their application to run on dedicated CITRIX servers, while a few others support sharing of servers with other applications.

The servers and clients run well-known operating systems such as Windows NT, Windows 2000, UNIX, and Open VMS. Due to the large installed base for these operating systems, obtaining vendor technical support and internal support is easy. Maintenance, management, and implementation of these systems are relatively trouble free as well.

System security will allow for multiple levels of access that is typically site configurable. At a minimum, a user will need an identifier and a unique password to gain access to the system. In addition, the capability to assign privileges to care givers using a common group profile based on a clinical function or a job title will be supported to enhance the security. Behind-the-scenes capabilities (such as audit trail) to track transactions and administrative tools to restrict read write privileges to the item level will be integral to the application.

Primary On-line Storage

Clinical information system specification for primary storage will include data storage capacity and redundancy, data security and reliability, and access time/response time. The storage capacity will be designed to support response time requirements with the capability of incremental expansion to meet changing clinical and operational needs. Real-time memory (RAM) and hard disk upgrades at the servers and clinical workstations will be supported by the architecture. In today's technology, large-sized disks (gigabyte capacity or larger) in the Redundant Array of Independent (or Inexpensive) Disks (RAID) configuration offer response time, capacity, and redundancy options that easily meet the demands of the clinical environment. RAID5 is one of the common configurations used in application servers that use at least three disk arrays designed for fault tolerance and performance. RAID5 provides data-striping (i.e., spreading out blocks of each file across multiple disks) with higher error detection and correction capabilities. The RAID configuration also allows hot swapping of failed drives, thus significantly reducing the system's down time.

Archive Storage

Clinical information system specification for archival data storage will include media technology, storage capacity and redundancy, data reliability, archival life, archival security, administrative control, and online availability /response time. The archival process, which will be transparent to the user, will be capable of archiving complete patient records without degrading system performance. The archive subsystem will be able to support data life over a number of years and data-availability guarantees, irrespective of changing media technologies and storage software. Access-security functionality will be consistent with the needs of the clinical environment and will meet the stipulation of the regulatory agencies. Write Once and Read Many Times (WORM) technology, once the most commonly used media in CIS configurations, are being replaced by Compact Disc Read Only media (CD-Rs). WORM media offer large-sized storage capacity (gigabytes) and require dedicated drives for reading them. CD-Rs offer portability and use of standard CD ROM drives at the expense of offering smaller storage capacity.

Integration

The communication network subsystem will support CIS requirements for connectivity, response time and data throughput, network maintenance, diagnostics, reconfiguration, reliability and continuous availability. The network will have a bandwidth capable of sustaining throughputs of 100 megabits/second or more, using connectivity protocols that are based on the open systems interconnection (OSI) model. TCP/IP (Kabachinski, 2003) and Ethernet protocols are commonly utilized in CIS communication network architectures. Network topology design and configuration will complement system guarantees in meeting response time criteria. In the area of connectivity, a single point of failure will not bring the system down; alternate routing schemes through redundancy will be part of the

architecture. Network availability should be continuous and consistent, with reconfiguration capability in case of a single link failure preventing propagation of network faults. Off-the-shelf components, such as hubs, switches, and routers, will form subsystem building blocks allowing for easy swap out of failed components.

Database

The database is a key component of the CIS architecture that dictates the level of flexibility offered by the system. Ideally, the Database Management System (DBMS) should be based on industry standard models, such as relational, object, or network, that are capable of communicating with other databases and statistical software packages in the health care enterprise. Most commercial CIS products typically use proprietary database architectures that will not allow users to import data items from external databases. Instead, commercial CIS products configure their databases with templates and data items that are user/site-customizable with the help of a configuration tool. The clinical-configuration tool will provide the user/site the ability to create new database items and clinical flow sheets that are closely tailored to their practice. In addition, CIS architectures will support real-time or batch/scheduled outbound interfaces for exporting clinical data to other foreign systems such as a data warehouse or to populate a foreign application such as an electronic patient record (EPR).

A natural query language type interface module will be an integral part of the DBMS and will provide the user with the ability to mine for clinical data for teaching, research, regulatory, and quality assurance objectives. An integrated online audit function that maintains a record of all user transactions (such as additions, deletions, or corrections made to the patient record) is required for risk management, litigation evidence, regulatory compliance, patient confidentiality, and privacy reasons. Most previous generation CIS database architectures did not support robust report writers; instead fulfilled both the database and reporting needs by exporting clinical data in ASCII (Kabachinski J, 2003) format to desktop software packages such as Microsoft Access. In today's market, CIS architectures have to offer an integrated report writer as part of the application. If not, at the very least, these systems should have the ability to interface to industry standard report writers. The state of the art in databases is the use of fourth-generation packages, such as Oracle, that are capable of sharing data with the environment more effectively and easily.

Application Software

The application software, residing on top of the operating system, is run from the server. This software is responsible for managing all clinical transactions, such as data acquisition, display and storage, print, and clinical configuration. The clinical configuration tool and the interface module are part of the application software. The complexity and flexibility of the application software is a function of the clinical data being managed, and also the extent of the clinical charting being done.

Clinical information is a mix of different data types. A patient medical record can consist of discrete laboratory results; continuous analog EKG waveforms; physician and nursing notes and summaries; vital signs trend graphs; radiological images and reports; and patient demographics. A robust CIS should be able to receive and process all of the different data types mentioned above and to integrate them to create a longitudinal electronic patient record. In reality, most systems provide connectivity to other systems that store specialized data. For example, image and waveform data are typically stored in the parent systems (such as radiology and cardiology), and the CIS will provide a pointer to these foreign databases. The pointers enable the clinician to pull up a snapshot of the image or the waveform for the patient alongside other clinical data. Although integration of all clinical data under a single product or single vendor solution is ideal, the fact that a CIS can interface to foreign systems for access to data not present in its database is a useful feature and it can provide a level of integration that is practical, without putting too much burden on the enterprise infrastructure.

Clinical charting is the documentation of clinical events that occurred during the course of a patient's care. One of the objectives of the CIS is to facilitate electronic

documentation of these events (Vegoda and Dyro, 1986). CIS databases usually come pre-loaded with most commonly used data items and document templates. Clinical documentation templates are time-based charts and visit-based forms with clinical data and are used by the clinical practice for patient care. These templates are readily usable or site-customizable with the integrated configuration tool. The configuration tool will enable the clinician to create new, site-specific data items and document templates, and also to modify existing templates in the database. A customization tool that is user-friendly and -intuitive will assist in the automation of current charting practices and, at the same time, will enable the user to take full advantage of the power of the computer system. For example, charting on a data item such as infant birth weight is essential for the mother-baby practice. Once the infant weight has been charted, conversion algorithms can be created to run in the background to present infant birth weight in different units of measure.

Clinical information systems should be able to add value to the clinical practice and to the health care enterprise. Reduction in documentation time as a result of automation can enable the clinicians to devote more time for patient care at the bedside (Subramanian et al., 1987). This could contribute to the improvement in patient satisfaction. Electronic charting can improve legibility and recoverability of the data, thus, greatly benefiting information management and reporting for compliance and regulatory needs. Most importantly, CIS can contribute to improvements in patient care, simply because of the availability of complete patient clinical information at all times. For CIS implementations to be successful, they also should be complemented by process redesign. The medication administration record (MAR) and physician order entry (POE) transactions, when computerized, are examples of process redesign that are necessary in order for an EPR implementation to be successful in the health care enterprise.

Medication Administration Record

The MAR is one of the most important tools used by clinicians in the health care setting. It is an abbreviated story of the patient's progress, struggles, and current condition that looks like a table with 31 columns, one for each day of the month and rows that are marked when medication is given (Institute for Safe Medication Practices, 2000). This flow gives all of the important information to safely give medicine. The MAR includes the patient name, name and type of medicine, dosage to be given, time given, name of the ordering physician, and the name of the person or persons dispensing the medicine.

Most vendors offering a clinical information system have an MAR integrated into their product. The very nature of automation enables the clinician to be able to update, review, and modify entries on the MAR from multiple locations and, in doing so, is not hampered by illegible handwriting or nonstandard abbreviations for medications. With a POE module in place, all of the transactions associated with medication orders can be tightly coupled, thus resulting in the reduction of medication errors. Integrating the pharmacy information system into this flow will complete the chain in the medication order-processing transaction.

Computerized Physician Order Entry System

The POE module can be an integral part of the HIS or a separate application that interfaces with the HIS for admission, discharge and Transfer (ADT) and billing information. The product that is most sought after today by health care enterprises in the United States is the Computerized Physician Order Entry (CPOE) for inpatients. This is due to the increase in medication errors reported by health care providers and also due to regulations that are calling for a reduction in medication errors (Kohn et al., 2000). To date, few hospitals have a fully implemented and functional CPOE in place.

CPOE is clinical software designed primarily to automate the physician-ordering process wherein the physician will now create patient orders electronically and no longer use paper (Leap Frog Group, 2003). The main focus in the industry today is implementing an electronic order entry system for inpatients. These systems allow the creation and maintenance of pre-configured physician order sets that are designed to speed up the ordering process. There are 8 to 10 vendors in today's market who offer CPOE solutions. It is important for a health care enterprise to choose the appropriate vendor solution because CPOE is at the beginning of the EPR implementation process. It is critical to ensure that the CPOE can be integrated with other EPR modules, such as clinical documentation, pharmacy, and laboratory. CPOE solutions today offer real-time decision support tools such as appropriateness of the order, ordering process, drug interaction and contra-indications prompts, advisory messages on limits, patient clinical and demographic information, dose calculators, industry standard drug reference database, and the ability to perform edits in real time. The decision making tool is a rules-based engine that can be activated, built on, and modified by the health care enterprise. In operation, the CPOE module is linked with other applications and databases that provide the necessary patient information.

Interfaces

Clinical information systems can no longer survive as dedicated departmental systems with their databases isolated from the rest of the health care enterprise. It has become increasingly necessary for these systems to be able to interface to ancillaries such as the laboratory and pharmacy systems and to the hospital information system. If the enterprise is planning on implementing a clinical data repository (CDR) and an electronic patient record (EPR), it is imperative that the CIS be able to share its data with the CDR and the EPR.

Clinical information systems should support industry standard interface architectures for information interchange with bedside monitoring systems, the hospital information system, and ancillary information systems. A patient medical record is a repository of data originating from disparate systems, and the main objective of an interface is to facilitate the sharing and exchange of data electronically between these disparate systems. For example, patient census (registration) from the HIS, lab results from the laboratory information system (LIS), medication orders from the pharmacy system, and vital signs data from the bedside systems, such as the physiologic monitors, ventilators, and infusion

pumps, are components of the EPR and are acquired by separate systems. Bedside system interfaces are different from the interfaces to hospital systems and, as such, merit a discussion of their own that is included under the physiologic monitoring system section of this chapter.

Information exchange with HIS and other ancillaries is normally achieved using the industry standard Health Level 7 (HL7) protocol (Health Level Inc., 1998). The HL7 communication protocol should be supported by the CIS interface architecture for information interchange with other systems in the health care enterprise. The HL7 interface uses layer 7 of the OSI (Kabachinski, 2003) model for information interchange, and an interface engine typically will serve as the translator for messages flowing between systems. The interface engine can reside on a separate server using third-party vendor software or can be an integral part of the HIS tightly coupled with other application modules. The CIS interface architecture should support, at a minimum, unidirectional ADT interface and bidirectional clinical orders and results (CORE) interfaces.

During registration, patient demographical and financial information, such as name, medical record number, encounter number for the visit, address, blood type, allergies, insurance eligibility, and referring physician are captured by the HIS. This HIS information is communicated electronically in real-time or batch mode to recipient systems such as the CIS by the ADT interface. The interface eliminates the need for this data to be re-entered as the patient moves across the enterprise. Physician orders for laboratory tests and medications are communicated to ancillary systems using an HL7 orders interface, which enables the clinicians to manage all patient orders electronically. Order information, which is also available to nursing, pharmacy, laboratory and other ancillary services, can populate other clinical tools such as MAR. Studies (e.g., Bates et al., 1999) have shown that there are significant reductions in medication order transcription errors as a result of using an electronic orders interface. A bidirectional-results interface based on the HL7 protocol will enable recipient systems like the CIS to receive results information, such as lab values, from the ancillary systems electronically. Finally, the CIS can send patient charges to the financial system using a billing interface to the HIS. All of the information received from the interfaces become part of the patient's medical record and can be shared with the EPR and the CDR.

Clinical information systems can reside anywhere on the capability curve depending on the functionality offered by the system. Although, applications such as pharmacy and laboratory have been implemented historically on dedicated systems, most vendors are moving away from that model. Vendors are beginning to offer a suite of applications, including laboratory and pharmacy, as part of their enterprise solution for an EPR.

Clinical Workstations

Clinical workstations are the interfaces that allow the users to interact with the system. They must be simple and user-friendly in order to be accepted and valued by the clinical staff. Using a personal computer (PC) for clinical transactions can be economical and sensible. The health care enterprise can manage the purchase, upgrade, and maintenance of the hardware for a much lower cost, as compared to deploying dedicated clinical workstations. At the user level, there is a definite improvement in acceptance, simply because of the popularity of PCs and the familiarity of the interface. Vendor applications support most popular PCs that are available on the market today.

Bedside Devices

Bedside devices include physiologic monitors, ventilators, infusion pumps, and others that acquire, display, and manage patient vital signs data in real time. All clinical information systems should support interfaces that are capable of acquiring real-time patient data from bedside interfaces because patient vital signs are an integral part of the patient's medical record (Subramanian et al., 1988a; Subramanian et al., 1988b, c). A more in-depth discussion of their capabilities and architecture is presented in the following physiologic monitoring systems section.

Physiologic Monitoring Systems

The process of monitoring a patient at the bedside and/or a central location can be defined broadly as the method of tracking continuously, in real time, the vital signs of a patient. In today's clinical environment, this is accomplished using a variety of bedside technologies, the most common and sophisticated among them being the physiologic monitor. The term "physiologic monitor," having been through many adaptations reflective of the device capability and functionality, is referred to as the "physiologic monitoring system" in today's world. As will be seen later in this chapter, these devices have grown so much over the years in sophistication, functionality, and intelligence that they have come to be known as "systems," as synonymous with "information systems." This is further proof that there is a convergence of what used to be traditionally a clinical engineering sphere of expertise, and what has come to be called "clinical information systems." The real-time aspect of a monitoring system is the only thing that sets it apart from an information system.

Some of the commonly monitored parameters include electrocardiogram (EKG); arterial and venous blood pressures (invasive and noninvasive); oxygen saturation using pulse oximetry; respiration; temperature; cardiac output; and, on occasion, parameters such as intracranial pressure. The age of the monitored patient population can range from a newborn to an adult, and the acuity of the patient population can vary from critically ill to ambulatory. Clinical settings can include tertiary care hospitals (Poppers and Dyro, 1985), ambulatory care clinics, community health facilities, nursing homes, physicians' offices, and ambulances.

The physiologic monitoring system (PMS) technology has successfully integrated a plethora of device functions into a single powerful bedside clinical tool. The obvious and measurable benefits are in real estate, single point of critical patient information, integrated alarm management, and unified user interface. Due to the single point of

connection, patient cable management is simpler. Although there is the possibility of a single point of failure, resulting in the loss of all functionality, there are definite advantages in areas of maintenance and parts and standardization. As there is a single point for data acquisition, communicating this data to other systems in the enterprise is less complicated.

PMS Architecture

PMS architecture can be classified in many ways. A monitor can be networked (wireless or coax cabled) or stand-alone, hardwired or telemetry, portable or fixed bedside, configured or user-configurable. One example of the state of the art in bedside monitoring technology is the Solar 8000M (Figure 98-2) product from GE Medical Systems.

Physiologic monitoring systems today are highly software-driven and, as a result, have become scalable to the type of care, type of patient, and financial constraints of the health care enterprise. At the same time, the hardware technology is moving rapidly toward the PC model with built-in connectivity features aimed at providing ease of integration within the health care enterprise. As health care institutions move toward a CDR and an EPR, bedside systems will be required to coexist and communicate with other information systems in the environment because clinical data acquired at the bedside will become part of the CDR and the EPR.

The monitoring systems should support a scalable architecture to match patient acuity across the continuum of care from the emergency department through the operating room and the intensive care unit to step down units (Poppers et al., 1986). These systems should be configurable to monitor neonatal, pediatric, and adult patient population. At the same time, they should be capable of meeting the needs of different patient care services such as cardiology, medicine, maternal child, mental health, and surgery, as well as dynamic units such as the emergency department, step down telemetry units, and specialty care services such as endoscopy and neurology.

PMS Components

The PMS comprises of the front-end data acquisition and processing subsystems, the user interface with the display and the output devices, and the back-end data and network interface subsystems. Under certain configuration, other components such as slave displays, tickers, and alarm processing units can be part of the PMS.

Vendors make every effort to include standards in their system architecture. Inclusion of standards at all levels of product design directly impacts scalability and post-implementation support, as well as the ability of the monitors to interface to a CIS. Modular design concepts are used to isolate functional blocks wherever possible. This can improve system up times significantly, as it will be easier and quicker to identify and replace failed modules in the field. Another important strategy is the use of off-the-shelf components and modules in the overall architecture. This reduces cost and vendor dependencies for parts and specialized peripherals. As a result of the adaptation of current standards and practices from the computer industry, bedside monitors have become intelligent data-processing and communicating systems—a far cry from the dedicated medical devices of just a few years ago.

Data Acquisition and Processing

The front-end data-acquisition and data-processing subsystems acquire and process the signals received from the transducers attached to the patient. The processed information, consisting of real-time analog traces and associated numerical values of the monitored parameters, are communicated to the display subsystem. Signal- and power-isolation functions (also part of the front-end subsystem) provide a high degree of isolation between the patient and power sources. The state of the art in the data-acquisition and processing subsystems (Figure 98-3) is the TRAM multi-parameter module from GE Medical Systems.

The front-end data acquisition and processing subsystems are a combination of analog and digital electronics and firmware written in machine and high-level languages. Significant benefits have been realized in real estate and power utilized by the hardware due to advances in semiconductor technology and digital signal processing. Very-large-

Figure 98-3 TRAM multiparameter module from GE Medical Systems Information Technologies.

scale integration has brought about a reduction in the number of discrete functional components and in the energy used by them for their operation. In today's PMS architecture, data acquisition and processing modules (largely hardware-driven in the past) are a combination of digital signal processing components and high-level software. As a result, systems are customizable to match the changing needs of the environment without compromising the functionality. Functional consolidation and technology integration, in addition to scalability, have also made the monitors smaller and modular. It is now much easier to install smaller monitors in tight and cramped spaces in hospital-patient rooms and nurse stations.

User Interfaces

Physiological Monitoring Systems support a variety of user interfaces that enable the clinicians to perform interactive tasks such as managing (e.g., admitting, transferring, and discharging) patients, changing alarm limits, configuring printers, storing and retrieving parameter trends, and monitoring remote patients. The interface should be intuitive and easy to use and should be consistent across all monitoring products used in the environment. The user interface, hardwired and wireless, should support the input of alphanumeric data and should serve as a navigation tool for selecting on-screen functions.

The acceptance and effectiveness of a specific interface technology depends on user education and preference. Most vendors offer a variety of user interfaces, such as standard keyboards, abbreviated keypads and trim knobs, front-panel buttons for the most commonly used functions, and wireless keyboards and keypads, and they try to maintain the same interface across all of the different models of their product line. The standard keyboard is most convenient for performing patient management functions because this process involves typing lengthy fields such as the patient's name and the medical record number. Obviously, keyboards take up the most space. Most care units use a combination of a standard keyboard and the trim knob, touch screen, or keypad for other routine transactions. Some vendors also offer wireless interfaces that are not hardwired to the monitor.

Display

The PMS architecture should be flexible when it comes to the display. The user should be able to choose the size (i.e., small, medium, or large), the technology (i.e., flat-panel or cathode ray tube), and the configuration (i.e., integrated or discrete) of the display that best meets the need of the environment. Trace resolution and trace separation are functions of the quality and size of the display, respectively. Larger monitors, which are capable of displaying color traces and bigger character fonts, are easy to read and more visible from a distance. Flat-panel displays are space savers and would be ideal for small and cramped locations. Finally, the architecture should support the use of off-the-shelf displays.

Output/Print

The PMS should support dedicated digital writers and laser printers. The user should have the flexibility to print alarm events, trend information, and on-demand traces on both printers. Most clinical printing will be done using the dedicated writers that are calibrated and scaled to provide true recordings of all the clinical traces. A laser printer, while providing a report-quality print out of clinical events, can also be shared by other applications when installed on the network.

Integration

A PMS vendor that does not offer network connectivity as a product feature is unheard of in the industry today. Distributed health care delivery systems demand the economies, functionality, flexibility, and interoperability that are achievable using standards for improving and maintaining the quality and competitiveness of their clinical practice and also for meeting their business objectives. A robust communication network is essential and critical for achieving these objectives. The PMS and other information systems in the enterprise are components on this network and, consequently, are required to adhere to industry standards and practices in implementing their architecture. Because physiologic

Figure 98-2 Solar 8000M Modular Patient Monitor from GE Medical Systems Information Technology.

monitors manage critical clinical data, loss of data due to collisions is unacceptable. A typical monitoring system network runs at 10 megabits/second with the network utilization ranging from 25%–30% of the total bandwidth. It is also not uncommon for the monitoring system to reside on a private network, totally isolated from the rest of the enterprise. The network security in this case is virtually unbreakable because the addresses are private and not accessible from outside the network. At the monitor level, all of the configuration functions are layered and are accessible only with a password. All of the functions required for routine management of the patient are at the user level and can be accessed by all of the clinical staff.

Interface

Bedside medical devices connect to the CIS using any one of three distinct configurations. The capability of the bedside system is the determining factor when it comes to selecting the configuration. One way is for these devices to connect directly to the CIS network. High-end devices like physiologic monitors can do this using their built-in network adapter and a unique network address. Low-end devices, such as infusion pumps, do not have this capability and require a host device to facilitate the network connection. Typically, physiologic monitors reside on a private network because of their up time and bandwidth requirements, while CIS servers and workstations are normally found on the enterprise network. As a result, although the monitors are network-ready for this configuration, additional dedicated hardware would be required to interface the monitor data to the CIS servers. This might not be desirable and most likely would not be cost-effective. In addition, transferring data across two separate networks poses real challenges when it comes to management.

A second model uses an intelligent multiport device to connect bedside devices to the CIS network. The multiport device is a node on the CIS network with a unique address. This commonly used configuration provides, at every bedside, the ability to connect multiple devices to the CIS network. This architecture also supports the integration of devices at all levels of sophistication.

A third way is for bedside devices, without network-interface adapters, to use a physiologic monitor to connect to the CIS network. The physiologic monitor, in this case, serves as a node on the CIS network using the built-in network adapter and the unique network address. This configuration requires the host device to handle network traffic while continuing to provide real-time patient information at the bedside. As a result, the primary function of the host device can be compromised, and consequently this configuration is less frequently used in connecting to the CIS network.

PMS Configurations

Hardware

Most patient care units have bedside and central station monitoring capability. In the hardware configuration, every bedside has a monitor that could be in one of the following modes or a combination of modes: Networked or stand-alone, configured or user-configurable, and portable or station-specific.

All critical care units are typically equipped with monitors at every bedside and at the central nurse station. The bedside monitors and the nurse station's monitor(s) are on a network and enable the clinical staff to manage patient care from both locations. The bedside monitor consists of a processing unit that is a node on the local area network; a color display that is capable of displaying six to eight real-time traces; a data acquisition and processing module with memory that is portable and patient-centric; a user interface such as a trim knob, keyboard or a touch pad; and a dedicated digital writer. The bedside monitors and the central stations form the local area network. These monitors typically are high-end devices that are capable of monitoring all of the vital signs simultaneously in real time with the ability to add or drop parameters to meet the changing acuity of the monitored patient population.

The data acquisition and processing module provides the link to the patient via patient cables and typically plugs into a base unit that has AC power and a link to the main processing unit. The beauty of the acquisition module is its ability to move with the patient while continuing to acquire, process, and display real-time data. This ensures continuous monitoring of patient vital signs during transport, without the clinician having to go through the cumbersome and time-consuming task of disconnecting and reconnecting patient cables for the transport. The acquisition module also saves the zero and alarm settings for parameters such as blood pressure from the bedside and eliminates the need for recalibration during transport and at the new location. The module continues to save patient alarm history during transport and at the new location. Thus, transporting patients between care units that are similarly equipped is quick, easy, and clinically beneficial. All that it takes at the destination location is for the clinician to unplug the module from the transport unit and to plug it into the base unit at the bedside. The storage capacity of the acquisition module is sufficiently large and can store a significant number of events and data trends for prospective review and print.

The enterprise can standardize all of the critical care patient rooms with the high-end monitors. As previously mentioned, in that case, moving patients between these units will be seamless. Their network capability will allow the clinician to view patient alarms and vital signs remotely and, when necessary, print trends and alarm histories. Alarm management in terms of setting limits and acknowledging alarms can be accomplished only locally at the bedside, although temporary alarm silencing can be accomplished from the remote location. The software allows the care unit and the clinical staff to configure the alarm capabilities of the monitor in one of two ways. All of the beds could be configured to the same default alarm strategy (e.g., parameter limits, acuity, audible and visual), based on the historical patient population admitted to the care unit. In this model, alarm settings are changed only for the specific patient, and the monitor will return to default settings after the patient is discharged. For the clinical engineering department, it is quite simple to document one set of default settings for the care unit and to use these settings when replacing a broken monitor. For the nurse in the unit, it is easy to cus-

tomize the specific bedside alarm settings on demand and not have to worry about keeping track of all of the original settings. Institutions that use this model typically store a copy of the care unit's default alarm settings at the nurse station and also in the clinical engineering department. One alternate method is to tailor each bedside to meet the acuity of the patient. This option is meaningful and beneficial for a floor with multiple care units. Obviously, it is tedious and time consuming and can contribute to potential clinical issues due to improper alarm settings. This model works well in small care units that have designated beds.

Configurability also plays a major role in designing the visual area of the monitor. This is the ability to decide the number of traces displayed by the monitor in real time, the order in which they are displayed, and their colors. This functionality, as well as the alarm configuration, is typically buried below the user level in what is termed the "service mode." The service mode is password-protected and can be accessed only by approved staff. Color designation to specific parameters can be standardized across the enterprise that can greatly improve both the visual comfort of the users and also the clinical separation of the different traces. The color option becomes clinically significant when monitoring parameters such as arterial and venous blood pressures.

Trace size, speed, color, and location on the display are customizable. The user sees, in real time, six to seven seconds of the real-time trace moving from right to left, complemented by numerical values and alarm limits for the monitored parameters. Alarm messages are annunciated audibly and visibly at the patient's bedside and also at the nurse station monitor. The alarm event also triggers the printing of 15 to 20 seconds of the trace, including six seconds of pre- and post-event data. One other feature that is useful clinically is the "view remote unit/bed" function. Because these monitors are on a network, they can be programmed to display traces from a remote bed in addition to the local bed. The local monitor display is on a split-screen mode, providing three to four seconds of real-time trace for the two beds. The remote view capability also can be extended to include the enterprise, allowing a physician to provide consultations for patients without having to go to the bedside.

The bedside monitors can also be configured as a cluster consisting of beds with patients with similar acuity or patients managed by a single nurse. The monitors in the cluster can be configured to share alarm messages with each other. This feature provides the clinician with the flexibility to make decisions with regard to responding to the alarms and can be clinically significant in areas where patients are spread out and also in areas where the patient-to-nurse ratio is high.

Ethernet and TCP/IP protocol are used for messaging by the local monitoring system network. The monitoring system network, running at a 10 megabits/second data transfer rate, uses CAT5 (Kabachinski, 2003) cabling and multiport hubs and switches for establishing connectivity between the bedside and the central station. For performance and response time optimization purposes, the local network architecture is designed to keep traffic within the subnet. Fiber-optic links provide high-speed (100 megabits/second) connectivity between the local network and other care units in the enterprise that are also on the private monitoring system network. Because the monitors reside on a private network, traffic generated by the monitoring system has no impact on the performance of the enterprise backbone. The high-end monitors, when used in a stand-alone configuration, will have no network connectivity to other bed-sides or the nurse stations.

Hardware monitors that are preconfigured with factory-set parameters are well suited for low-acuity care units. Preconfigured monitors are typically single, integrated units consisting of the processor, display, and patient and network interfaces. They are less expensive, as compared to the configurable monitors, and they can be deployed in stand-alone and network modes. With no central station monitoring capability, the stand-alone mode is suitable for care units that have a high nurse-to-patient ratio. In the networked mode, these monitors find wider use where the central-station monitors are capable of displaying vital signs for all of the patients in the unit.

Preconfigured and configurable monitors can reside on the same local monitoring network. Unlike the high-end monitors, the preconfigured monitors do not have the detachable acquisition module that can go with the patient during transport. As a result, during transport, the clinician will have to take the preconfigured monitor from the bedside or use a separate transport monitor for monitoring patient vital signs. Using the preconfigured monitor for transport will necessitate bringing in a new monitor to the bedside. On the other hand, using a transport monitor will require the clinician to swap patient cables and zero transducers before the transport and after the patient is returned to the bedside. There will be a break in patient monitoring during transport using either monitoring modes. In this case, if ever there were a need for retrospective review of the data, the history of events that occurred during transport will not be a part of the continuous record.

Another major advancement in monitoring technology has been the integration of 12-lead ECG measurement function. With the latest physiologic monitors, the clinician can initiate and complete a 12-lead ECG measurement at the bedside, like all other vital signs for the patient. In the past, this function was managed by the EKG department in cardiology and required dedicated EKG technicians and specialized equipment such as the EKG carts. Because EKG carts used a unique set of patient cables and leads, it was necessary to change patient cables and leads whenever a 12-lead ECG was performed on a patient at the bedside. The physiologic monitors, with 12-lead ECG capability, have enabled health care institutions to decentralize the EKG departments and to reduce their staff because nurses and residents are now able to perform this task at the bedside. By standardizing cable, leads, and bedside monitor software version, hospitals can ensure 12-lead ECG capability across the enterprise.

Telemetry

As the phrase suggests, in the telemetry monitoring mode, there are no monitors at the bedside, and patients are managed from the nurse's station using central monitors. Telemetry monitoring is commonly used to manage less-critical patients who are able to (and sometimes required to) ambulate. Current telemetry systems are capable of monitoring in real time, 5-lead ECG, noninvasive blood pressure and oxygen saturation. One example of the state of the art in telemetry monitoring (Figure 98-4) is the Apex Pro Telemetry System product from GE Medical Systems.

Figure 98-4 Apex Pro Telemetry System from GE Medical Systems Information Technologies.

A telemetry monitoring system consists of transmitters, antenna subsystems, receiver cabinets and central station monitors. The transmitter, attached to the patient, sends real-time digitized vital signs data over a radio-frequency (RF) carrier signal. A network of antenna subsystems, installed at strategic locations in the care unit for maximum coverage, communicates the digitized data to a set of receivers for processing. The central monitor located in the nurse station displays and trends the real time information. All patient transactions, such as admitting, transferring, discharging, alarm configuration, and printing are performed and managed at the central station. The patient also can initiate a print transaction from the transmitter.

The central monitors store alarm events and parameter trends. They can be complemented by dynamic ticker displays and slave monitors placed strategically around the unit. These complementary displays can provide up-to-date patient status information to the clinicians when they are away from the nurse station. The slave monitors display the same information as the central station.

The telemetry configuration requires dedicated staff at the nurse station to monitor the patients and to alert the clinicians when there is a change in patient status. Clinical staff in the telemetry unit will use the hospital paging system to alert the clinicians. Step-down care units typically have a high patient-to-nurse ratio and also a high patient turnover every day. The acuity of the patients in these units, in many cases, calls only for telemetry monitoring. It is also likely that patients from multiple-care units located on different floors are monitored centrally from one nurse station. The total number of patients managed at these nurse stations can be upwards of 40. The biggest challenge in this environment of high patient turnover and inadequate staffing is to keep the clinicians informed of the changing status of their patients.

Fast and reliable methods to communicate alerts to the caregivers are available in the market today that communicate alarms from a monitoring station to the alphanumeric pagers carried by clinicians. These systems reside on the same network as the telemetry receivers and the central monitors, receiving patient alarm information in real time, just like the central monitors. They are programmable to send alarm messages to one or more pagers, depending on the severity of the alarm and the responsibilities of the clinician. The alarm messages include the patient's name and room, as well as the date, time, and type of the alarm. The system can be programmed to send alarm messages from selected patients to a designated pager and a backup pager. Management reports generated by these systems can provide data on frequency and response times for different alarm categories that can be utilized by the institution for implementing changes in clinical practice and adjusting staffing levels in the unit. Note that these alarm communication systems were designed and sold only as adjuncts to the traditional monitoring systems and that they cannot replace the role of dedicated and knowledgeable clinical staff.

The telemetry receiver cabinets and central monitors can reside on the same network with hardware monitors. Because bedsides can be configured for both telemetry and hardware monitoring, the clinician can tailor monitoring system capability to the acuity of the patient. Patients on telemetry and hardware monitoring systems can be viewed on the same central station monitor, and managed from one nurse station. This flexibility significantly reduces the need for moving the patient within the unit and greatly benefits bed-management operation. Because both the telemetry and hardware systems use the same patient interfaces (e.g., cables and leads), patient discomfort is also greatly reduced when switching between the two systems. Intermediate care units, with varying patient acuities, are usually equipped with hardware monitors and an antenna network for the telemetry system for this very reason.

Wireless

A third mode that uses wireless communication technology finds use in certain areas of health care enterprise. The wireless configuration lends itself to non-station specific locations such as hallways, bathrooms, waiting rooms, and other overflow areas that otherwise would not be considered monitored locations. A highly fluctuating patient census in a hospital may require that monitoring capabilities be available at these locations. Furthermore, staffing and environmental constraints may require these locations to be monitored centrally as well. The hardware and telemetry monitoring modes require the installation of permanent connections or an antenna network at these locations, a

significant overhead cost for the enterprise because there is no certainty of ever using these locations for patient monitoring. In addition, there is no real way to estimate what would be a sufficient number and location for overflow beds and, as such, in the case of a disaster, there still could be a shortage of monitored locations. The wireless architecture makes the monitoring devices non-station-specific and truly enables the clinicians to bring the monitor to the patient.

Spread spectrum and cell phone technologies are used in implementing the wireless architecture. Every patient monitor and central station is equipped with the transmitter/receiver pair that is capable of sending and receiving information from all devices that are part of the cluster. This configuration does not require connection locations, and, as such, it can be used to monitor patients anywhere in the unit, including the hallways, waiting rooms, and even bathrooms. In the past, the wireless data channel was able to monitor only a limited number of parameters, due to bandwidth limitations. That is no longer a limitation, as these monitors are capable of handling the full range of patient acuity and can be deployed in most care units in the health care enterprise.

Most hospitals use a combination of monitoring modes to accommodate the clinical, as well as financial, needs of their practice. It is imperative that the different monitoring modes and technologies coexist in the environment and also communicate seamlessly with each other.

Other Monitors

Transport Monitoring Transport monitors are compact, portable monitors with limited capabilities, as compared to bedside monitors. The state of the art in this area is small, lightweight displays that are capable of accepting the data acquisition modules from the bedside monitors and displaying up to four real-time traces. Patient transfer is seamless because there is no need to recalibrate transducers and no need to disconnect and reconnect patient cables to get the patients ready for transport. One example of the state of the art in transport monitoring (Figure 98-5) is the DASH 4000 product from GE Medical Systems.

The transport monitors run on batteries and manage alarms in the same way as the bedside monitors. In effect, the transport monitors can serve as bedside monitors when there is a need, and they provide clinically acceptable levels of monitoring and care. Typical battery life is an hour, and under certain configurations the battery life can be increased with the addition of a second battery. All care units that use the transport monitors should have a charger base(s) to plug into, to charge the batteries.

Central Station Monitors Central station monitors are capable of displaying data from multiple patients at a central location such as a nurse station. For this to happen, the bedside monitors and the central station monitors should be on a network. Each central monitor can display two-real time traces per patient for up to eight patients continuously. Patient transaction, such as admitting, discharging, and alarm acknowledgement can be performed at the central station. In fact, in a telemetry unit, all patient transactions are done at the central station because there is no user interface at the bedside. The central station can display all patient alarms and can save and print user-selected patient events. An example of the state of the art in central station monitoring is the CIC Pro Clinical Information Center product from GE Medical Systems.

Windows NT-based workstations that are capable of running multiple applications are the state of the art in central station technology. These stations are capable of launching applications that run in the background without compromising their primary function as real-time patient monitors. Consolidating applications will result in the reduction of hardware clutter in clinical areas and, at the same time, translate to cost savings for the hospital in replacement hardware and technical support. With the help of a couple of key strokes, users will be able to navigate between the real-time patient vital signs information, a 24-hour, full-disclosure software and a HIS terminal emulation session to review patient census and laboratory results. These Windows NT stations support industry-standard laser-jet printers that can be shared between applications.

Figure 98-5 DASH 4000 Transport Monitor from GE Medical Systems Information Technologies.

PMS Enterprise Integration

Integration of bedside monitoring systems with the rest of the health care enterprise is rapidly gaining in importance. Patient demographics (registration) such as name, age, and sex are being brought to the bedside monitors from the HIS using industry standard HL7 interfaces. Similarly, 12-lead EKGs performed at the bedside monitor are being transmitted electronically to the cardiology information management system. Once the EKG is read and confirmed by a physician, a charge for the service can be sent to the hospital financial system to generate a patient bill. In both cases above, a working interface will be required that is available in today's market.

There is also the convergence of functionality between traditional noninvasive cardiology functions, such as Holter recording and the full-disclosure feature of the monitoring system. In the full-disclosure mode, a dedicated workstation on the monitoring system network acquires, stores, displays, and prints beat-by-beat vital signs data. These data can be retrieved within the 24-hour window for retrospective analysis of events. Holter recording, a modality where patient EKG is acquired and stored over a period of time for retrospective analysis and reporting, is accomplished using the 24-hour full-disclosure monitoring modality of the physiologic monitoring system.

The architecture of the monitoring system lends itself to better management of patient parameter alarms. Alarm messages are more commonly managed from a central location and, in some cases, such as the intensive care units, are managed at the bedside. In addition, care units that use telemetry to monitor their patients use other remote tools, such as pagers, tickers, and slave displays. Hospitals have also started using PCs for alarm management. A PC, running dedicated software, can be a node on the monitoring system network communicating critical patient alarms to alphanumeric pagers carried by clinicians. The message sent to the pager contains information on patient identity and location and also on the acuity of the alarm. As a result, clinicians can make decisions on responding to the alarm without having to rush to the patient's bedside. This tool is useful and beneficial to care units that are short-staffed and also to units that use telemetry for patient monitoring. The alarm histories and response times tracked by the computer can be used by management for quality assurance and process improvement objectives.

Physiologic Monitors and Clinical Information Systems

Previous generation monitors used proprietary connectivity architecture and as such, extracting data from them by external systems was difficult (Subramanian et al., 1988a). The design focused mainly on pushing data from the bedside for viewing at the central station, and no standards were in place, either for the network architecture or the data-communication interfaces. Over the years, the function of a monitor has changed from a display unit to that of an integrated information management tool. Vendors have been enhancing the capabilities of the monitors to meet the demands of clinical environment to the point where they have become powerful bedside computers ready to communicate with other computers in the enterprise. To some extent, this evolution has also been influenced by the demand for bedside data from regulatory and benchmarking agencies. Physiologic monitoring system vendors have risen to meet this challenge by integrating information technology standards in their architecture. In the health care environment today, data acquired at the bedside, such as the 12-lead ECG, are also impacting the financial status of the health care institution. It is all the more important for the bedside monitors to be able to integrate and interface with other systems in the enterprise for sharing and exchanging of clinical information.

Most clinical information systems are able to interface to bedside monitors to receive vital signs data in real time, and also to track clinical trends. They also interface to the HIS to create a patient medical record with important identifiers, such as name, medical-record number, address, and age, and the vital signs data acquired from the bedside are linked to this patient record. In this model, bedside devices are identified by their physical location, such as room number, and the data association with the medical record is achieved when the patient is admitted to that location. This is functional and workable only if the bedside devices are on the same network as the CIS. In the case of physiologic monitors residing on private networks due to bandwidth requirement and up-time guarantees, HIS patient-identifier data can be routed to the monitors using dedicated gateways. The monitors themselves should have the software capability to receive and populate these data fields in order for this to happen. The state of the art in bedside monitor software is still evolving in the area of field edits for patient demographic information and in interfacing to information systems for demographics data, order processing, results reporting, and billing. The need for this enhanced capability at the bedside is being driven by clinical and financial pressures, and vendors are beginning to address it by incorporating features in the monitors to meet specific applications.

One such application is the acquisition of 12-lead EKG using the bedside monitor. The EKG carts receive the physician's order and patient-demographics information from the HIS, and charges are dropped on the HIS financial systems after EKGs are read and confirmed. As discussed earlier in this chapter, bedside monitors are also capable of transmitting 12-lead EKGs to a cardiovascular information system (CVIS) for interpretation and confirmation. Most bedside monitors today allow users to enter demographic information (e.g., patient name, age, medical record number, care-unit name, and bed location) using the "admit" function. Current software versions for the monitors do not qualify this data as mandatory or required fields by providing screen edits, thus permitting the clinical staff to skip fields or even to enter incorrect information. As a result, EKGs are transmitted from the monitor to the CVIS with missing or incorrect patient identifiers. Patient EKGs without proper identifiers are not billable and result in loss of revenue for the health care institution. There is also the serious matter of noncompliance because patient EKGs without identifiers are not usable for diagnosis and care. A second problem is the inability of the bedside monitor to store real-time 12 EKG traces. Monitors display real-time parameter waveforms continuously, including six to eight

seconds of EKGs, and only store alarm events and parameter trends for retrospective review and print. Because 12-lead EKG waveforms are not stored by the bedside monitor, the decision to transmit them to the CVIS must be made by the clinician in real time. If subsequent EKG traces are cleaner and clinically significant, the only option for the clinician is to transmit these traces also to the CVIS. Because every 12-lead EKG requires an order from the physician, this results in multiple EKG traces for one order. Given the volume of 12-lead EKGs done on any given day by a large institution, it is nearly impossible to manually match up the appropriate EKG trace with the order. Unresolved EKGs are not billed because they are not read and confirmed, and they are also not available for clinical use. The last problem is the inability of the interface gateways to queue EKGs when there is a loss in connectivity between the monitoring system network and the CVIS. EKGs are communicated to the CVIS from the bedside monitors by dedicated workstation(s) acting as gateway(s). In most health care enterprises, the CVIS resides on the hospital network, and the gateways provide the connectivity between the private monitoring network and the hospital network. When the gateways go down or lose connectivity to the CVIS, 12-lead EKGs from the bedside are not transmitted to the CVIS. These EKGs are not recoverable even after the link is re-established between the CVIS and the gateways. Gateway software with buffering capability complemented by a redundant system can eliminate this problem.

Vendors have been slow to come up with a solution to these issues. Gateways, with upgraded software, are now capable of storing EKGs over a period of days when there is a loss in connectivity with the CVIS. A typical 12-lead EKG file size is 5 kilobytes, and the gateways are able to store a significant number of EKG waveforms while waiting for connectivity to be re-established with the CVIS. Bedside monitors can now acquire patient demographics information electronically from the CVIS using the "admit" function. Because the CVIS already acquires the ADT information from the HIS for order processing and results reporting, the bedside monitors can be populated with the same information when a clinician requests that information using the monitor's "admit" function. Errors due to manual data entry are no longer a concern, and the likelihood of the CVIS receiving EKGs with proper patient identifiers is high.

Bedside monitors' capability has not been upgraded to store 12-lead EKG traces. This feature will provide the clinician with the ability to select from the stored EKG traces. After reviewing the stored traces, the clinician can select the appropriate trace for transmission to the CVIS. At the CVIS end, as there is only one ECG trace per physician order, reconciliation and billing from that point forward will be easy.

The orders and results interfaces between the HIS and the CVIS complete the circle as far as processing 12-lead EKG transactions are concerned. EKG orders entered on the HIS are electronically sent to the CVIS using the HL7 protocol and are electronically matched by the CVIS with the EKGs sent from the bedside monitors and the carts. After the EKGs are interpreted and confirmed, a message is sent back to the HIS, acknowledging completion of the transaction and authorizing dropping of the charges. While real-time EKG traces are stored in the CVIS, results that consist of measured and calculated parameters and interpretation text can be sent to the HIS, an EPR, and a data repository. Installing the CVIS client application at workstations located throughout the enterprise will enable clinical staff to view and print confirmed 12-lead EKGs. Because all aspects of the 12-lead EKG process are captured electronically and stored in one system or another, medical records departments are no longer required to store paper traces or to microfilm them.

Clinical Engineering and Clinical Information Systems

Bedside devices today are data and information management systems, and not just bedside monitoring tools. To a large extent, this came about as a direct result of advances in technology. Health care institutions have come to recognize the role of bedside devices as important sources of data that are being sought after by regulatory, provider, and benchmarking agencies. As a result, clinical engineers, traditionally and historically responsible for the management of these devices, have been forced to modify their role in the enterprise. Their focus and skill sets must be retooled to meet this changing environment.

The traditional inspection, preventive maintenance and repair (IPMR) model is not necessarily the only support model, nor is it practical due to the changing technologies and changing dynamics of the health care landscape. Electrical safety is still an important consideration in the design and ongoing maintenance of these devices, although digital technology advances in hardware design have significantly reduced the risk to the patient in this area. Implementation of functions in firmware and software coupled with large-scale integration in semiconductor technology has led to reduction in space and power consumption. Medical devices have benefited from the transfer of this technology, as is evidenced by the shrinking footprint and increasing functionality of the devices. Repair and maintenance, for the most part for many of the devices, should be a matter of identifying the failed module and replacing it. Most medical devices also store error codes in real time to assist in the quick and easy troubleshooting of a failed module or device.

Medical devices have become data and information management systems that are connected to each other (and, potentially, to foreign systems). On many occasions, it will be necessary for clinical engineering departments to look beyond the immediate device to identify, isolate, and resolve problems. This effort calls for additional and, in some cases, different skill sets. It will be necessary for the clinical engineering profession to expand its role and also to hone its skill sets to meet these new challenges offered by the health care enterprise.

One easy way to meet the changing needs is to integrate the clinical engineering department with the information technology (IT) division. In this model, the traditional role of the clinical engineering staff will be preserved because other IT staff will be responsible for resolving all issues behind the device. This model severely restricts the opportunity for CE departments from foraging into cutting-edge technologies (such as network infrastructure) that could provide new career opportunities for CE professionals.

Proactive CE leadership can convince hospital administration of their readiness and willingness to meet these new challenges.

The distinction between a computer system and a medical device can become insignificant in the near future, and the possibility of the two technologies merging is high. One can envision a single workstation at the patient bedside that can pull up, on demand, patient clinical events such as alarm history and trends and that can perform clinical-information transactions such as lab orders and results, vital signs flow sheets, and others. With a single sign-on and context-switching capability, the workstation can be a powerful clinical tool. In addition, this approach greatly reduces the clutter around the bedside by freeing up space.

A great need exists for improving the skill level and overall education of the technical staff within the CE departments to be able to meet these emerging challenges. In addition to the knowledge base, CE departments will be required to find ways to participate actively in the selection, implementation, and management of these systems. Communicating and interacting with other professionals will become increasingly important. Technology will require clinical engineers to work closely with information technology professionals. Communicating effectively with the IT staff will be important.

First, CE professionals must learn about networking and computer systems. Networking fundamentals, such as operation of hubs, switches, and routers, will be useful tools in understanding how information is exchanged on the network. Basic education in network topologies and OSI standard on network layers is a requirement. After hardware failures, the second most common problem with bedside monitors today is configuration. Frequent operational issues, such as inability to print, missing beds at the central station, inability of the bed to communicate with other beds in the unit and with the central station, and an inability to see remote beds are network- and configuration-related. Today's monitors are highly configurable to the needs of the specific patient and offer flexibility in the area of sharing resources such as printers. Having a firm understanding of software fundamentals will be useful in troubleshooting many of these problems.

The concept of IP addressing is commonly used in the monitoring network communication architecture, and it is imperative that the CE technologist understands how to use the IP function to resolve basic connectivity issues. The central stations are computers that run operating systems such as Windows NT and that are capable of running other applications in the background. The CE technician should have a working knowledge of the operating system environment in order to be able to invoke certain transactions at the command level, monitor error logs, configure printers, and reallocate resources. The management of the monitoring system network, for example, will be a shared responsibility between the CE and IT departments. In most cases, the CE staff will get the first call when there is any monitoring system problem. The CE staff should be able to isolate the source of the problem within the scope of their responsibility before triaging it to the IT staff. Lastly, understanding the technology, the concepts, and the jargons will assist in troubleshooting a problem while following instructions from the vendor's technical support over the phone.

In teaching and research institutions, individual researchers will demand real-time data from monitors. CE staff should have a good understanding of the communication protocols and their configurations. Most monitors will support a serial interface that can be used to connect a computer for data acquisition. In some cases, the computer can be assigned a fixed IP address to become a node on the monitoring network, and then can be programmed to listen to communications from a specific device or devices on the network. This can be a problem if the computer uses the same IP address as another valid and live device on the network, such as a monitor or a central station. Because the monitoring network uses dedicated IP addresses, the possibility of duplicate IP address is not unlikely and staff must be guarded against it. The CE who has the appropriate education and experience can support the research application without compromising the real-time patient care function of the monitor.

Changing Role of Clinical Engineering Departments

Clinical Engineers and their hospital departments have a new and important role to play when it comes to automation in the clinical environment (Bronzino, 1992). The bedside monitoring systems and other medical devices (such as infusion pumps) are important sources of patient and clinical data that populate the patient's chart, and clinical engineers are the experts within the enterprise on the management of these devices. Integration of the medical device network into the enterprise backbone for data interchange is critical, and in order to be successful there must be a seamless and cooperative working relationship between the CE and IT departments. Here is a tremendous opportunity for CE staff to educate the IT staff with their expertise in clinical device technologies. To be accepted in the new role, CE departments must enhance their knowledge base and expertise in enterprise-technology solutions, such as system integration, communication protocols and standards, hardware, and software architectures. The trends in the medical device industry and marketplace are on a convergence path with IT, and it is in the best interest of the clinical engineering departments to get onboard at the front end of this change must prepare their staff to recognize and embrace the challenge. A proactive CE leadership will inform and educate its staff about the changing role, will provide the staff with technology based continuing education, and will offer its services in enterprise-wide projects.

Health Insurance Portability and Accountability Act

The federal government's mandate under the Health Insurance Portability and Accountability Act (HIPAA) for compliance in areas of privacy and patient confidentiality when it comes to access to, and communication of, identifiable patient information has a major impact on CE departments. In fact, CE departments will be required to support the compliance initiatives of the health care enterprise because of the medical devices that are managed by them (see Chapter 104). Similar to the Y2K situation, the number of medical devices (stand-alone and networked) vastly outnumbers the computer systems that exist in the health care environment. A number of types of these medical devices display, save, and transfer patient-identifiable data that are covered under the HIPAA requirements. CE departments will have to be proactive in classifying the medical devices by the type of data they handle and assigning levels of risk (Marchese, 2002). Obviously, the level of risk will determine the necessary corrective action for compliance, and clinical engineers will play an important role in this area.

Advanced Diagnostics and Artificial Intelligence

Donald F. Blumberg

President, D. F. Blumberg & Associates, Inc.
Fort Washington, PA

Over the last decade, there has been a significant increase in the development, application, and use of advanced diagnostics and artificial intelligence technology in field service. Research* carried out in the early 1980s, in fact, showed that service problem diagnostics could result in avoidance of between 30% and 35% of all on-site field service calls, and that in-depth diagnostic evaluation could significantly reduce the number of "broken" field service calls through more intelligent dispatch and assignment of both parts and service engineers (Blumberg, 1984). Since that discovery, there has been a great deal of work carried out attempting to both develop and apply advanced diagnostics technology in the field service industry. It is, therefore, of value to examine both the *current* state-of-the-art and the experience in the application and use of problem diagnostics and resolution technology in the health equipment field service industry, as well as to pragmatically explore both the successes and failures of artificial intelligence and advanced remote diagnostics and decision support methodology in service. This analysis is summarized in this report.

An Overview of the General State-of-the-Art in Remote Diagnostics

The role of artificial intelligence (AI) and remote diagnostics in the service environment is usually part of the overall call-managing process and is based on the strategic use of information and data acquisition methods to identify, isolate, analyze and, ultimately, diagnose and evaluate a fault within a unit of equipment or system. The goal is to increase the efficient allocation and timeliness of service-oriented resources, and to raise the productivity of the service force and the up time of equipment through efficient use and deployment of service personnel and parts to support the up time objective. Improving performance in the service function relies on having the most efficient technology to find, identify, isolate, predict, and repair a fault or potential fault. This requires a service organization of such sophistication as to fully exploit the available and potential benefits of the diagnostic maintenance practice in technological depth.

In general, service productivity can be improved in four ways:

- The anticipation of potential future failures through predictive and preventive maintenance to initiate field work that avoids emergencies and unanticipated failures
- The reduction or elimination of actual, on-site, service calls through more efficient problem and fault diagnosis in response to an emergency call requests and prior to emergency call dispatch.
- The use of improved fault diagnosis to optimize the site-dispatched calls by identifying the required craft and skill levels and parts
- The reduction of on-site repair time through more rapid isolation of the actual problem

The underlying issue is the acquisition and use of information to diagnose and refine the service-call decision as part of the call-handling process, prior to actually initiating the on-site service visit. The data acquisition methods used, and means by which that information is manipulated and presented, represent the technological focus of artificial intelligence and remote diagnostics today in service. Within this context, the maintainability of the database is the most critical issue in terms of utilizing diagnostic knowledge bases; as knowledge bases become increasingly complex, due to the inclusion of ongoing subsequent data, the maintainability of these systems becomes a key factor. Knowledge bases must be constructed to ensure reliable diagnostic information within the limits of a maintenance system.

As such, the more intense and detailed a knowledge base can be transformed, proportional to the cost that will be incurred, to ensure its maintainability. This can be applied in terms of breakdown maintenance/emergency repair, preventive maintenance, and predictive maintenance.

In the traditional practice of breakdown maintenance and emergency repair (Figure 99-1), the information that is used to diagnose the equipment or system fault is usually obtained post facto. Costs associated with breakdown and emergency-repair maintenance practice include unanticipated production losses and related costs of idle production

inventory, wasted and wrongfully allocated craft and manpower, and down time and damage of associated machinery resulting from the initial failure.

Preventive maintenance, in which maintenance is scheduled at regular time intervals, provides significant levels of protection from catastrophic equipment failure (Figure 99-1), however, it may be creating unreasonable costs due to assigning parts replacement or overhauls, when the equipment may be operating well within desired operating parameters. Manpower costs can be concurrently overextended by the preventive maintenance approach. Information used in the design of a preventive maintenance schedule is typically taken from the manufacturer's original design and maintenance specifications data. Optimally, the preventive maintenance schedules will be tempered by the personal experience of the responsible maintenance engineer.

Predictive maintenance is condition-restricted. Service provided when the equipment's operating condition is shown to be deteriorating toward catastrophic failure. These condition-monitoring methods are dependent upon the criticality of the equipment and the equipment function, the ability to apply sensors to monitor conditions and to communicate that data, and the volume of information that is needed to be interpreted to make a competent service decision and predictions.

The primary tool for acquiring accurate information in predictive maintenance is the use of condition-monitoring techniques to assess the operating "health" of a particular piece of equipment, or equipment system. Condition-monitoring typically utilizes measures such as:

- Vibration analysis (fast Fourier spectrum analysis)
- Temperature
- Fluid flow/volume
- Pressure
- Electric current fluctuation

Preventive and predictive maintenance can provide service when it is not required, increasing the costs of equipment service. The condition-monitoring approach, while requiring a cost to implement the monitoring apparatus, could optimize the usage of service, providing maintenance and repair only when critically necessary to maintain the equipment's up time integrity. In general, preventive and predictive maintenance works best for mechanical and electromechanical equipment that fails gradually. Demand repair works best for equipment that is either working or not working (i.e., electronic technology).

The actual use of remote diagnostic tools and practices in service has occurred consistently in several places within the full service call process architecture.

- The most common diagnostics mechanism is the technical assistance center (TAC). The TAC typically will have a staff of experts complemented with technical documentation and possibly with access to diagnostic-based systems. The TAC will provide end-users with initial call handling and will implement any call-avoidance routing (e.g., talking the end-user through the solution, sending a user-replaceable part or, when required, beginning the service call escalation system procedures).

The overall call management system with remote diagnostic typically contains:

- One or more help desks or call management centers
- Technical assistance centers (TACs) linked to a help desk
- Local area networks (LANs) connecting to individual workstations in both the help desk/call center and TAC

In developing an integrated approach to call management and TAC systems, five general functional modules are necessary, including:

1. The *configuration management* module that is required for overall network control as it provides the ability to identify online and locate hardware/software components
2. The *troubleshooting module* that provides the ability to examine information from the LANs, PC controllers, and other devices through the use of integrated diagnostics
3. The *problem tracking and trend analysis module* that provides the ability to track all supporting activities and responses by configuration as well as identifying long-term trends in problems or service calls

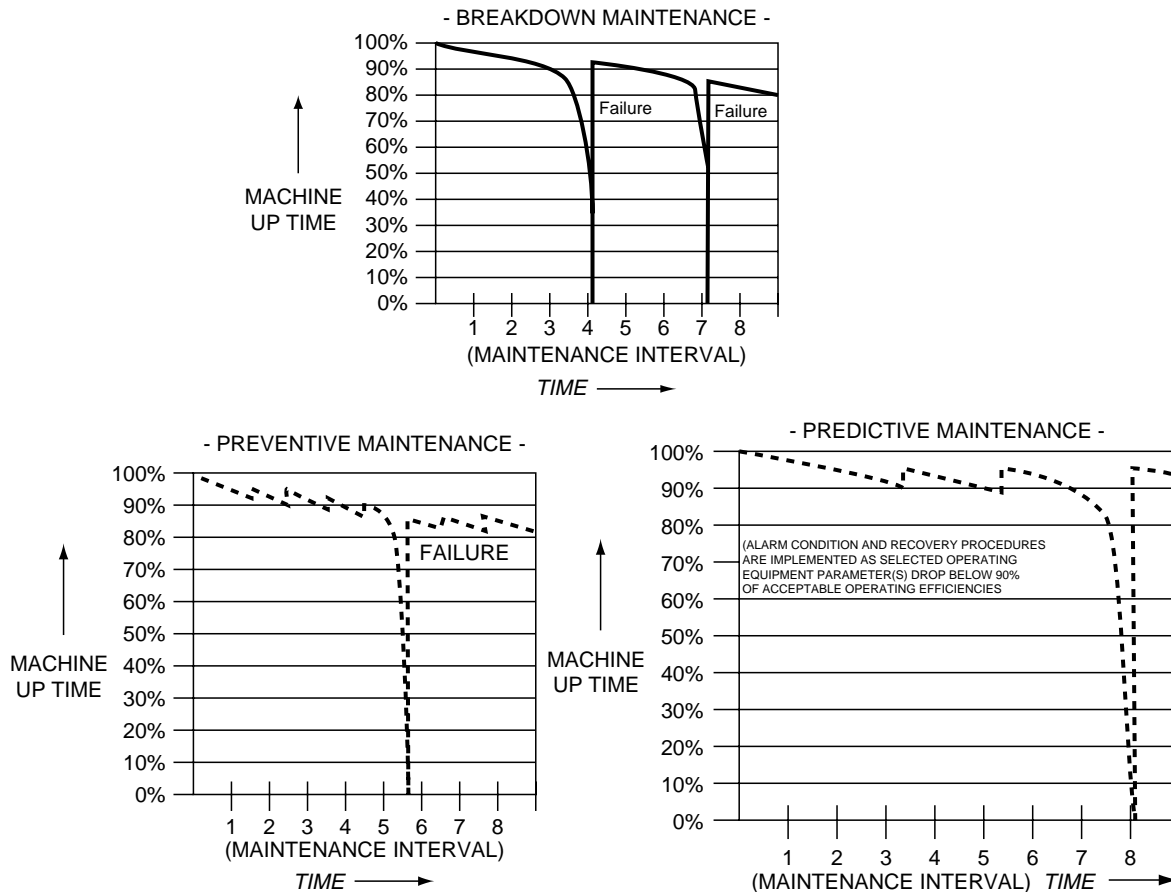

Figure 99-1 Illustrative example of maintenance and repair practices on equipment up time.

4. The *software control module* that provides the ability to support the process for loading new programs, controlling system enhancements, and enforcing software-version control
5. The *shared and coordinated peripheral resources module* maintains complete tracking of the status of reporting and printing in the system

In examining the typical customer configuration and need for service and the business environment in which service operates, one will observe a variety of calls arriving as a function of the stage and the life cycle of support of the system; the extensiveness and sophistication of the system; the size of the deployment; and the education, training, and sophistication of the user group.

The general classes of customer service calls (Figure 99-2) fall into the following categories:

- Type 0—Systems Designs, Specification, and Integration Requests

- These calls tend to be related to new or emerging requirements and are often random in nature, and are typical of the types of calls that would occur during the very early stages of a system development project.

- Type 1—Installation

- The actual start of system specific and general customer requests. These calls will occur at the point of installation after system approval, design, and integration. These calls often relate to scheduling of the implementation, installation, initial training, and concerns over workability.

- Type 2—Maintenance and Repair Service Requests

- The typical customer call in this category involves requirements for maintenance and repair services due to hardware failure, software failure, or a combination of hardware and software failure. These calls are not only very critical but also tend to be those that are perceived by most service organizations as the primary type of service call request. However, the pattern of call arrivals for Type 2 calls is quite different from the call patterns for other types of calls and the mechanisms for response are also different.

- Type 3—Instructional and “How to” Customer Calls

- A new class of customer requirements and needs, emerging as a result of the increasing sophistication of the system, the fact that increasingly, systems are being used in “real time” by non-technical personnel, and that initial instruction at the point of installation might be either not as comprehensive, or as in-depth as required, relates to user questions concerning the application and use of the equipment, or user inexperience, or lack of user understanding of a specific or general application.

- These instructional and “how to” calls tend to be critically important in terms of the overall service delivery process to the user, but it is equally important to avoid confusing Type 3 calls with Type 2 calls since the mechanisms, delivery approaches, and optimum-handling mechanisms are quite different. In addition, many service organizations tend to see Type 3 calls, as “non-critical” or, even worse, as “not our responsibility.” However, from the user perspective, these calls are just as important and critical as Type 2 calls.

- Type 4—Network Calls

- A new class of customer calls now occurring, as a result of the increasing deployment of sophisticated local and wide-area networks, are those relating to failure of the network as a whole or elements of the network.
- Because the general user, particularly in the distributed mode, is unable to determine that the cause of his problem could be a network-type failure, rather than a failure or problem in his own unit, these calls are also often perceived as Type 2 or Type 3 by the customer/user. In addition, the service organization can easily misinterpret these as “Type 2” calls unless some particular technical screening and network-oriented evaluation process is put into place. In essence, the failure of either a local or wide-area network can generate a very large number of Type 2 calls by individual users. An appropriate problem-resolution and self-organizing data system can discern relatively easily whether this rapid series of arriving calls is, in fact, network-related and can “flag” such calls, in order to avoid further work to try to fix the individual box that is failing to operate, due to a network failure, rather than to a box failure itself. The service organization system must be able to recognize this problem as network-related and must direct its focus on the network “fix” if it is to avoid being overwhelmed by inaccurate Type 2 or Type 3 calls from individual users.

- Type 5—Moves, Adds, Changes (MAC) and Field Improvements

- These calls are usually generated as a result of the change in systems’ environments and/or user needs. In that sense, they tend to be very similar to Type 0 calls.
- Alternatively, they could be self directed as a result of a pattern or statistical analysis and evaluation of the demand associated with Type 2, 3, or 4 calls that tend to dictate the need for a field engineering change or modification in hardware, software, or network, structure and topology in the field, in order to reduce or eliminate certain types of problems in the future

In general, the character of the total demand pattern of these calls is well defined. The total demand pattern for all calls per day is quite predictable as shown in Figure 99-3.

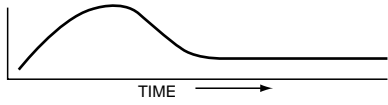

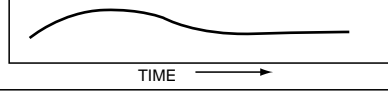

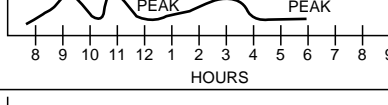

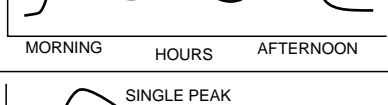

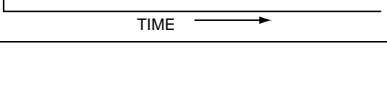

TYPE	SERVICE	LIFE CYCLE TIME FRAME	LIFE CYCLE PATTERN
0	DESIGN / CONSULTATION	MONTHS	VOLUME 
1	INSTALLATION / DELIVERY	MONTHS/ DAY	VOLUME 
2	OPERATIONAL, MAINTENANCE AND REPAIR	DAYS	VOLUME 
3	INSTRUCTIONAL, "HOW TO" AND GENERAL QUESTIONS	DAYS	VOLUME 
4	NETWORK	DAYS	VOLUME 
5	MOVES, ADDS, CHANGES	MONTHS	VOLUME

Remote Diagnostics State of the Art

Work in the field of advanced remote diagnostics and artificial intelligence in the field service industry initially tended to focus on the use of “expert” oriented decision techniques based upon either rule or “heuristic” expert models and processes. Within the last few years, there has been a further extension of this array of technology to include self-organizing systems and processes, as well as the application of new intelligent data storage and retrieval approaches. The general process now can be described in the model shown in Figure 99-4.

Within the explicit active remote diagnostic advisory systems are more specific mechanisms, as outlined in Figure 99-4, including: General fault models, troubleshooting models, and deep casual models. The differences between these approaches are outlined below:

- *General fault models* show all the ways that a device can fail and the casual linking among the failures. Information about applicable tests and repairs is attached to each fault situation. This approach has been shown to be not very useful for new products and technologies repair diagnostics.
- *Troubleshooting models* are usually augmented fault models that follow the pattern of the general fault model above but also describe how the fault diagnostics strategy should be modified, under certain conditions. In general, troubleshooting models add “if-then” logic to the standard fault model to support repair analysis.
- *Deep casual models* actually describe the way the unit under repair is structured and assembled. The knowledge base describes the way the device is put together, the way it works, what the relationships are, how likely each piece is to fail, and generates a troubleshooting strategy, based on these relationships. These models are most often used where the equipment being diagnosed is very new or highly complex or where little or no effective troubleshooting strategy currently exists.

In addition to model-based expert systems are rule-based expert systems that involve either flow charts or procedural rules that can be used to diagnose a repair situation, or the use of decision tree technology. The decision tree concept, outlined in Figure 99-5, is based upon the use of a tree-like structure that can relate machines or products to complaints to symptoms to causes and, ultimately, to corrective action recommendations. This type of analysis can be carried out before any type of repair action is completed, (i.e., *a priori*) by reliability and maintainability engineers, to construct the “tree” and “branch” relationships without actual experience. Alternatively, a call handling, dispatch, and call closeout process could be established, making use of the same decision tree structure on a *post priori*, or after-the-fact, basis. This is easily done by simply linking information on the arriving calls for service in terms of identified product or machine related to complaints and symptoms, and then, ultimately, tying this information to a specific closeout call relating the cause to the symptom and the ultimate corrective action that resulted in a fix or repair.

In substance, decision trees could be built before repair actions through reliability analysis or through reverse-engineering analysis. In this case, they are being used in the context of a rule-based expert system. They also could be built-in to the call handling process to construct actual decision trees based upon completed and closed out call data, in the context of a self-organizing approach. Recent developments in the design and application of self-organizing systems also have focused on parallel and sequential processing, utilizing a combination of logic, hypertext, and parallel processing to achieve the same solution as utilized in the *post priori* decision tree-approach described above.

A third major area of technology applied in diagnostics is to make use of newly developed intelligent (data-) retrieval systems. These approaches attempt to use high-speed computer technology to search existing files for case-based situations that are similar in nature to the diagnostics being executed or to make use of neural networks or use very high-speed hypertext search.

All three approaches attempt to make use of historically collected data to present the correct and appropriate information to the repair provider, either centrally or in the field. In summary, the current state of the art involves two general types of structure (i.e., retrieval and diagnostic advisory systems), and two types of explicit diagnostic systems (i.e., expert systems and self-organizing systems).

Expert systems are the other category of advisory systems. Expert systems provide an architecture for recording and using the experience of “expert” human service engineers:

- Rules-based expert systems are produced by recording and linking the heuristic decisions that are made by the human mind when problem-solving or troubleshooting a unit or system’s fault, based on “*a priori*” or before-the-failure analysis. Literally, this approach documents the minute steps that a service technician must go through to remedy a fault. Typically these systems are structured to work on a forward-chaining or a backward-chaining logic depending upon the specific problem for which the system was designed to solve
- Model-based expert systems are also developed on an “*a priori*” basis from a database of the system’s or unit’s calculated or anticipated failure structure and behavior. This format makes the model-based approach better suited for the fault analysis of new equipment that service personnel might not be familiar with; methods to add historical information as it is developed are desirable in a model-based expert system.

Within this diagnostic state of the art, the basic process model for call resolution and fault diagnostics and isolation, as shown in Figures 99-6 and 99-7, follow these procedural steps:

- Gather and collect information to determine the symptoms and situation in which the problem appears
- Form a hypothesis to select a fault that is most likely to have caused the observed symptoms
- Select a goal or set of goals to resolve a particular call derived from the hypothesis that would have been previously developed this step usually takes the form of

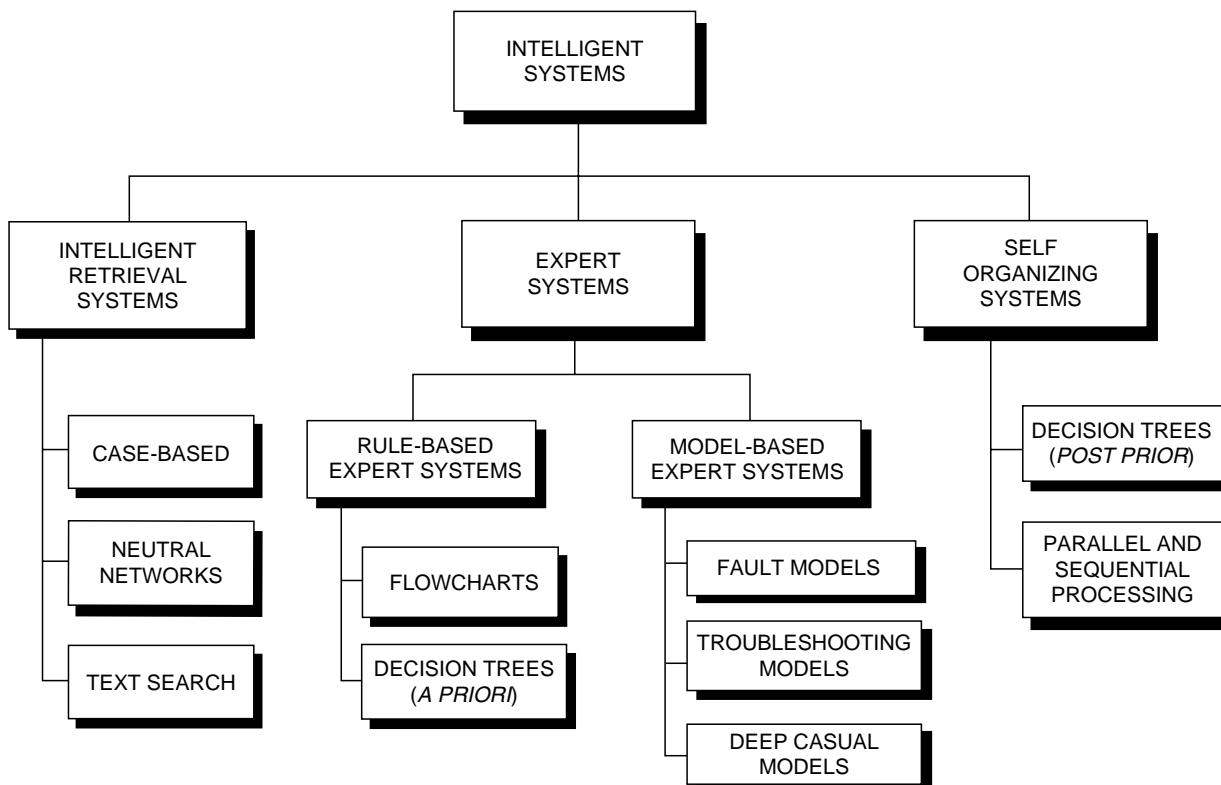

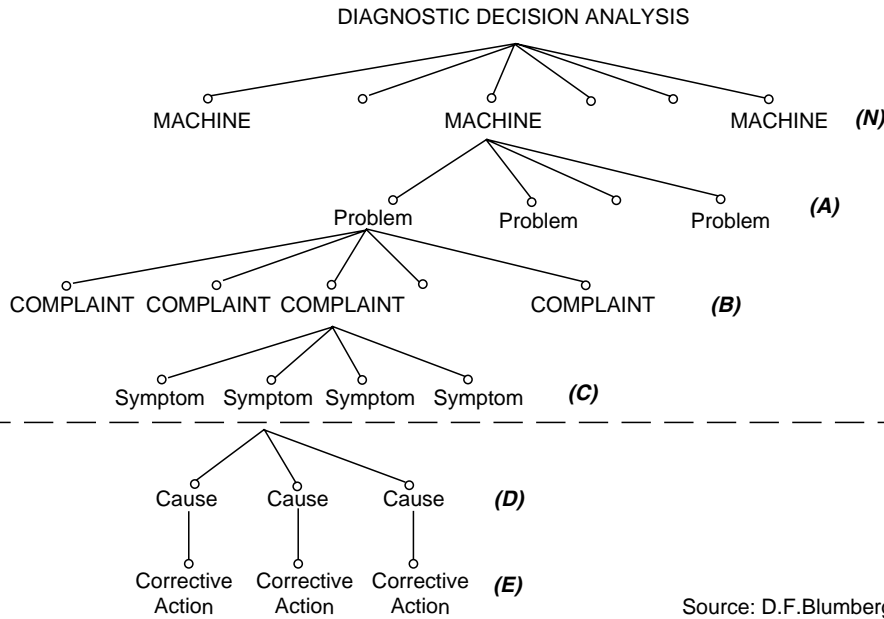

Figure 99-4 Overview of types of data and intelligent diagnostic systems used in help desk/TAC.

Source: D.F.Blumberg Associates, Inc.

Figure 99-5 Basic diagnostic decision analysis tree structure.

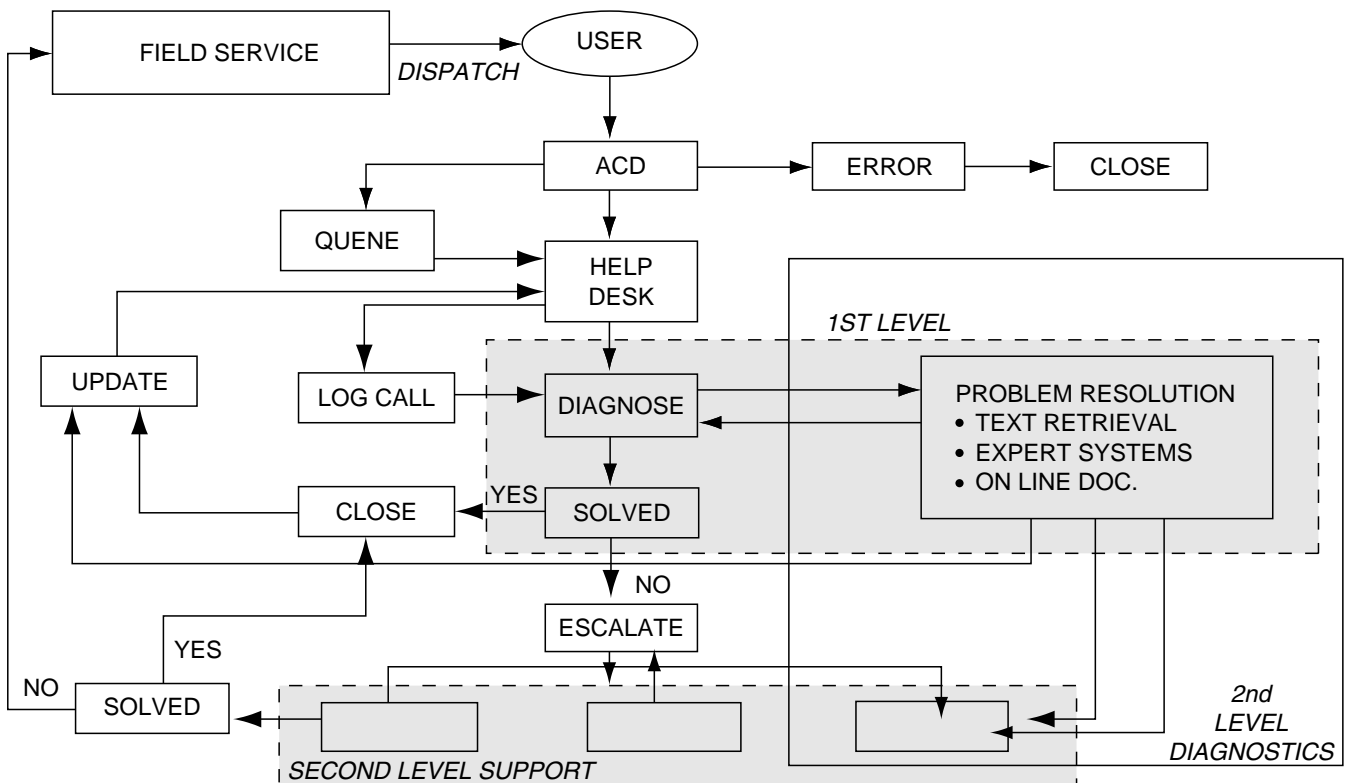

Figure 99-6 Diagnostics process flow model.

- “determine whether element x is faulty;” by selecting specific parts out of all the parts to blame, making the process much more manageable and leading to a faster resolution
- Determine which action would most efficiently guide towards achieving the selected goals. The action might be diagnostic, by observing certain values or indicators, or performing a test, or it might be repair-oriented, such as calibration, cleaning, or replacing a part

- Performing the action recommended, and observe its results. If, for example, the action is repair-oriented, observation usually will require repair verification, or retesting functions of the equipment that failed to see whether the repair action caused these functions to work
- Analyze whether the actions’ results strengthen or weaken the current hypothesis. If the hypothesis is strengthened and is specific enough, then the problem can be identified and resolved. Otherwise, the hypothesis must be refined, and the process must be repeated

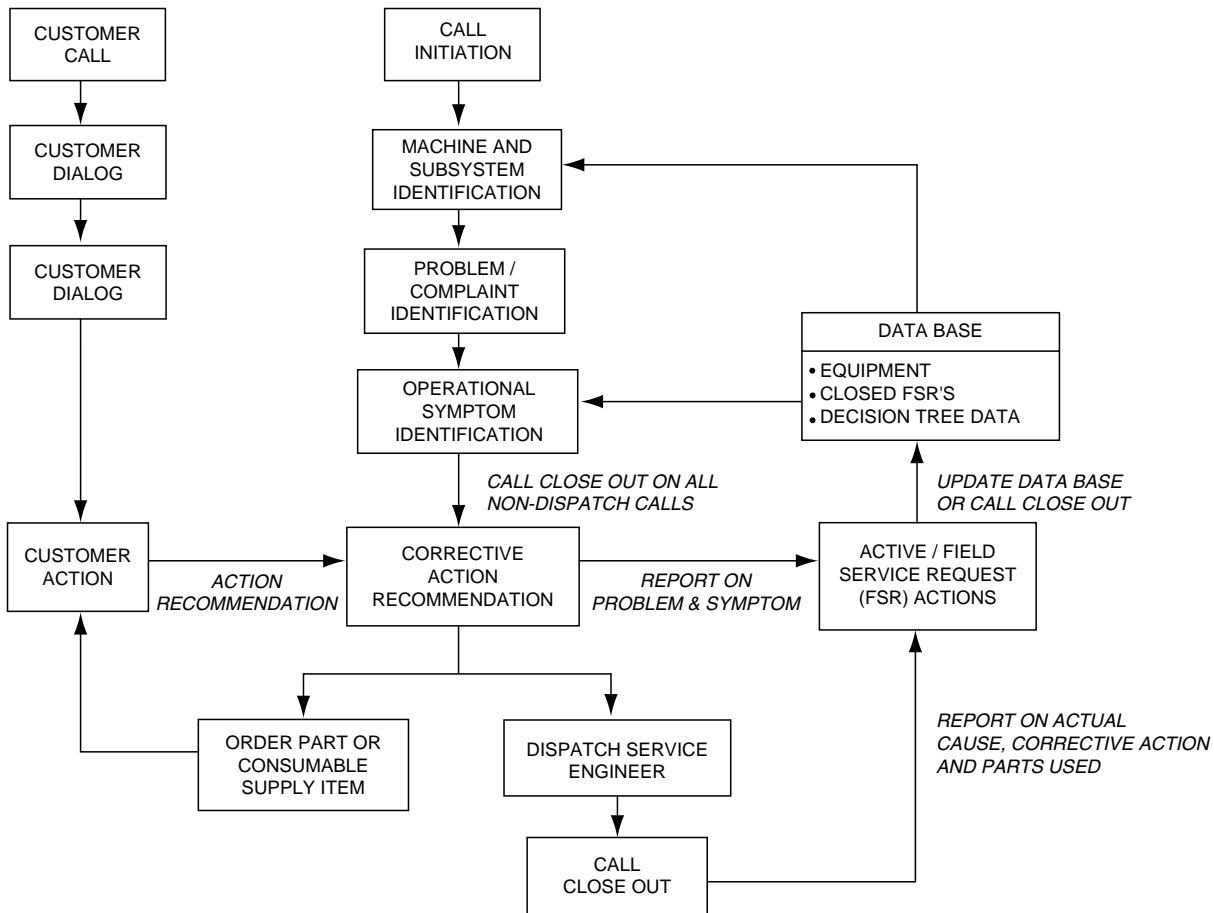

Figure 99-7 Remote diagnostic (decision support) process flow in help desk/TAC application.

The above fault isolation process requires extensive knowledge of the serviced equipment; service engineers obtain such knowledge from formal training, on-the-job training, accumulated experience, and equipment manuals. Several trends, however, make it difficult for service engineers to obtain and to preserve all of the knowledge required to perform their jobs most efficiently. One such trend is the rising complexity of modern equipment. Another is the number of different types of equipment that each engineer must service: Different manufacturers, different models from the same manufacturer, different versions of the same model, each one requiring a large amount of knowledge to be instantly available.

The results of these trends are increasing service costs and decreasing service quality. Because service costs and perceived service quality have immediate and important effects on sales and profits, many companies have decided to search for service support tools.

The application potential will vary as a function of type of diagnostic approach and by the product technology employed, as well as by the application. For example, mechanical and electromechanical equipment tends to fail gradually, and thus expert systems can have value in identifying requirements for predicting the need for advance maintenance. This preventive and predictive maintenance approach has proven to be of some value, particularly for equipment such as heating, ventilation, and air conditioning (HVAC), medical technology, and building automation. Diagnostics and troubleshooting for electronics products tend to be on more of a "go-no-go basis" and therefore self-organizing systems tend to have greater value in these applications. The overall assessment will, obviously, change over time with new breakthroughs in the diagnostics and artificial intelligence state of the art, and as a function of commitment to apply the technology for various types of products and systems. From practical industry experience, it appears to be correct to say that retrieval systems and the self-organizing systems have a role in service and that the applicability of the technology will vary as a function of type of product (e.g., electronic, electromechanical, or mechanical), and the stage of product use (e.g., new product rollout versus mature product versus product being phased back). Specific examples of technology application by company are shown in Figure 99-10.

Current Overview of Diagnostics Technology in Field Service

In field service, a variety of new products to support diagnostics and repair decision making have arisen as a result of extensive developments in the area of remote diagnostics technology and artificial intelligence. These products seek to improve service-based

troubleshooting and repair capability for call and help desk-based diagnostics and call avoidance, TAC support, and support in the field. These are shown in Figure 99-8. Fully integrated help desk and technical assistance centers (TAC) systems are also available separately, on a stand-alone basis or as part of an integrated field service management system program.

Direct Experience in the Impact of Diagnostic Technology on Health Technology Service Productivity and Efficiency

As indicated above, there have been significant increases in the commitment of funds by vendors and field service organizations to the development, application, use, and roll-out of advanced diagnostic technology in field service. While the overall demonstration of significant, quantitatively measurable, impact is.

Since 1998 or so, considerable work has been done on developing customized remote diagnostics technology for use within the medical technology field. The key leaders in this area include General Electric Medical, Picker International, Elscint, and Medic Engineering and Maintenance Services (now part of Innoserv). Most use the remote diagnostics in service as a competitive differentiator.

General Electric

General Electric (GE) Medical offers remote diagnostics on CT scanners and MRI through its in-site service program. In-site is targeted to high-end, top-of-the-line equipment including GE9800 CT Scanners, Signa Advantage MRI, Starr Nuclear Imaging, and Advantx Digital X-Ray.

The technology includes a microprocessor, bidirectional modem, and software attached to equipment at the customer facility. The customer telephones the GE customer service center located in Milwaukee, Wisconsin, available through the computer-assisted, repair and engineering services (GE CARES) program, to report a service malfunction. GE CARES alerts and dispatches an in-site technician that patches into the customer's equipment via modem. The technician uses in-site analysis software and database (expert systems) to diagnose the problem. In many instances, a solution can be provided over the telephone.

Service calls that require on-site repair are transferred back to the GE CARES dispatch center by the in-site technician, who schedules a service call and assigns necessary parts. A limitation on in-site is that it is more conducive to identifying software problems than hardware, because GE's equipment is not designed to allow in-site to inspect hardware circuitry. Furthermore, in-site is essentially a reactive diagnostic tool that is primarily geared for operational problem-resolution such as shutdowns created by a power surge.

Figure 99-8 Comparative analysis of vendors of diagnostic products vendor capabilities.

In response to market demand for proactive remote diagnostic tools, GE developed quantitative system analysis (QSA) for Signa Advantage MRI customers with access to in-site. QSA essentially monitors equipment, usually after hours, to detect system problems by performing regularly scheduled computer-to-computer checkups, including an automated analysis of each subsystem of the imaging equipment.

QSA enables the operation of two proactive diagnostic tests:

1. A "top-level test" is a weekly evaluation of the entire system. It includes signal-to-noise ratio and other parameters. Results are benchmarked against standards and are compared against other GE Signa MRI units. Data are reported back to original the customer.

2. Small sample test analyzes subsystem performance with the goals of faster calibration and allowing the service professional to troubleshoot on-site.

In-site is available to GE service technicians and service contract customers free of charge. GE maintains "proprietary" rights to diagnostic equipment/system technology attached to the customer's equipment, thereby limiting access to noncontract customers and unauthorized personnel.

The benefit to customers in utilizing in-site is the lowering of downtime costs by lowering repair time from 1.5 hours to 15 minutes. However, the ultimate benefit is realized by GE because in-site lowers costs of labor (dispatch of technician, travel time) and capital (spare parts carrying costs). Note that in-site does not eliminate the role of the field

technician. It merely provides a “first line of defense” by performing an initial analytic/diagnostic check.

Picker

Picker’s remote diagnostic tool for CT scanners is an expert-based system named Expert. Expert is a portable computer system that field representatives can use to modem into computers at the Picker service center. The interactive link enables step-by-step diagnostic routines. Expert is primarily used by Picker field engineers and support staff. The system is licensed for a fee or sold under exclusive contract to end-users. Picker will train hospital in-house service staff in the use of Expert.

The company resists use of Expert by third-party maintainers (TPMs) because TPM overheads are generally lower. Use of Expert would enable TPMs to gain a significant competitive advantage, which would not be in the best interest of Picker management

Mediq

Mediq, an Arlington, Texas-based independent medical imaging service provider (now part of Innoserv) uses its own proprietary remote diagnostics called Memserv. Memserv (whose name means Mem’s evaluation, repair, and verification) utilizes a PC at point-of-service to download the service software to the CT scanner. It collects hard data by interfacing with the hardware and analyzes data to identify problems or help in calibration.

This technology replaces GE advanced diagnostic service software that is not available to independent service organizations (ISOs). It was developed out of necessity and from a strategic decision and investment to be state-of-the-art and on the leading edge by developing its own software.

Elsclint

Elsclint has applied the Rosh (ServiceSoft) developed expert system shell called CAIS, for computer aided intelligent service, applied to diagnostics of Elsclint nuclear imaging technology. CAIS is basically a database that relies on an ongoing feedback loop of knowledge, acquisition, storage, and delivery. This system, marketed by Elsclint under the name Mastermind, has been applied to Elsclint’s Apex nuclear medicine system.

Mastermind requires a service expert to enter data related to operation and service of particular medical equipment. It is user-friendly, and no programming experience is required.

Mastermind, based on Advisor, a diagnostics expert system, identifies problems and recommends appropriate solutions through a PC. The system logs data regarding the service call to the point-of-service allowing CAIS customers the ability to download this experience data into original database.

Benefits that accrue to Elsclint from the Mastermind system include enhanced up time, faster service calls, faster PM, expediting entry-level technician training, and reducing loss of expertise from turnover of senior technicians.

Cost Benefit and Impact of Remote Diagnostics

Full quantifiable measurement of remote diagnostics cost benefits has yet to be pragmatically demonstrated in a broad sense. However, it is, clear that diagnostics technology does have some measurable impact. A comprehensive study of the primary benefits and impacts of service diagnostics in equipment service showed an array of primary and direct

benefits and impacts, as indicated in Figure 99-9. These benefits can be measured in terms of improvements in service delivery as viewed by the service provider, the field service organization, and the customer.

A survey of well over 100 service providers indicated that service diagnostics can reduce the training time and can reduce or eliminate the effort required to collect and analyze repair and maintainability data. Diagnostics also can help the service organization directly in improving the allocation of craft personnel and parts resources, to reduce costs. Diagnostics technology also has been found to provide a way to deliver better service and product differentiation to the customer from the perspective of the service providers identified above and customers (based upon a survey of over 250 customers). Additional direct benefits include reduction in the overall mean-time-to-repair, including a reduction in the number of “broken” calls due to a lack of availability of parts or skills on-site. Finally, the service providers and the customers observe that service diagnostics could be used to improve the ability to deliver service in remote or inaccessible areas. Quantification of these benefits was more difficult, however.

The primary direct benefit of diagnostics, as shown in Figure 99-10, was the creation of a competitive advantage, reduction in mean-time-to-repair, and reduction of the number of “broken” calls. This was most directly measured in terms of the reduction in the total elapsed time for repair in complex calls, which is typically about 20% of the total number of calls carried out by service organizations in the computer, building and plant automation, and medical electronics service markets. Where measured, diagnostics also tended to increase the up time and the mean time between hard failures. Finally, the survey of service organizations suggested that the best delivery mechanisms were via laptop or portable devices through deployment directly to field service engineers.

In summary, a final area of the D.F. Blumberg & Associates’ survey analysis related to the current use and future plans for development of diagnostics in the field service industry and the observable cost savings or benefits used to justify diagnostics products in field service and to evaluate return-on-investment (Figure 99-11). In this respect, the Blumberg studies compare favorably to similar results found in the Serviceware study (1991) of remote diagnostics. Generally, both studies suggest that the use of diagnostics technology varies dramatically by industry with the highest level of implementation being in the industrial control, building- and plant automation markets, telecommunications, and computer industry. There is also a high level of investment occurring across the board to examine the applicability of diagnostics technology for future use.

Actual pragmatic experience in cost savings or benefits justification utilized in diagnostics products tends to vary as a function of the technology serviced and supported as well as the basis of focus (Figure 99-12). In the past, general justification was based upon the concept of gaining a competitive edge over other service organizations, capturing and retaining expertise and knowledge, and improving telephone troubleshooting as part of a TAC operation. These more qualitative justifications tended to be utilized in more cases than direct cost or time savings with respect to reduction in training time, mean time to diagnose and repair, and in the number of calls (e.g., broken due to lack of parts or technical skills). It is quite clear that additional experience will be required before direct quantitative measures of cost benefits can be utilized in justification with a high degree of accuracy and confidence.

In essence, as shown above, the overall justification and impact of diagnostics technology in field service, as of this time, is still based mostly on “soft” issues although there are clearly some specific situations and instances where the savings have been substantial.

COST JUSTIFICATION BASIS	TECHNOLOGY			
	COMPUTERS & OFFICE AUTOMATION	TELECOMMUNICATIONS	MEDICAL ELECTRONICS	BUILDING & PLANT AUTOMATION
GAIN GENERAL COMPETITIVE EDGE	55%	35%	50%	64%
CAPTURE & RETAIN SOME EXPERTISE/KNOWLEDGE	41%	45%	48%	55%
IMPROVED TELEPHONE TROUBLE SHOOTING	35%	42%	28%	31%
IMPROVED CALL AVOIDANCE	31%	43%	21%	34%
REDUCED TRAINING TIME & COSTS	21%	18%	14%	21%
REDUCED MEAN TIME TO DIAGNOSE AND REPAIR IN FIELD	37%	28%	19%	34%
REDUCED BROKEN CALLS DUE TO PARTS/TECHNICAL SKILLS	31%	21%	22%	20%
OTHER (INCREASED REVENUE, JUSTIFICATION OF ADDED PRODUCT VALUE/PRICE)	11%	10%	12%	10%

Figure 99-9 Observed specific cost savings and/or benefits in cost justification based on actual diagnostics projects implemented.

BENEFITS	EFFECTS
IMPROVED CRAFT AND RESOURCE	REDUCED PERSONNEL AND PARTS INVENTORY COSTS
REDUCE THE TRAINING TIME AND SKILL LEVELS OF MAINTENANCE	REDUCED LABOR COSTS PER MAINTENANCE PERSON
REDUCE OR ELIMINATE EFFORT REQUIRED TO ANALYZE DATA	REDUCED PERSONNEL REQUIREMENTS
REDUCE OR ELIMINATE EFFORT REQUIRED TO COLLECT DATA	REDUCED PERSONNEL REQUIREMENTS
REDUCE ELAPSED TIME REQUIRED TO ASSESS PROBLEM; REDUCE MTTR FOR BOTH DEPOT AND FIELD REPAIR	REDUCED PERSONNEL REQUIREMENTS IMPROVE UPTIME
IMPROVE PREDICTABILITY OF FAILURE IN ORDER TO INITIATE PREVENTIVE MAINTENANCE PRIOR TO EMERGENCY FAILURE; INCREASE MTBF	IMPROVE UPTIME INCREASE PERSONNEL REQUIREMENTS
IMPROVE RESPONSE TIME OF SERVICE CALL AND/OR CALL AVOIDANCE ROUTINES	GREATER CUSTOMER SATISFACTION CUSTOMER RETENTION
IMPROVED CRAFT AND RESOURCE ALLOCATION	REDUCED PERSONNEL AND PARTS INVENTORY COSTS
GREATER SERVICE AND PRODUCE DIFFERENTIATION	POTENTIAL TO GAIN NEW MARKETS AND IMPROVE POSITION IN CURRENTLY SERVED MARKETS

Figure 99-10 Benefits of use of advanced diagnostics and AI technology for service operations.

In summary, remote diagnostics technology has been shown to have a direct cost-benefit impact on the service and support organization, and the service user. The impact is, by far, the greatest on the service and support organization.

The primary observed impacts are on the following:

- Creation of a competitive advantage and reduction of direct competitive threat by ISOs
- Reduction in mean-time-to-repair
- Reduction in field diagnostics and troubleshooting time
- Improvement in dispatch assignment and allocation
- Reduction in number of broken calls due to lack of parts
- Improvement in ability to detect the need for field changes and/or field modifications,
- Better control and allocation of high value, critical parts inventory

Remote diagnostics technology is usually implemented via either internal development (as in the case of DEC, Honeywell, Texas Instruments, Johnson Controls, and GE.) or external purchase of software on either an off-the-shelf or customized basis (as in the case of Elscint, Varian, U.S. West, Bailey, and Siemens.).

The effect on the service organization varies primarily as a function of the implementation approach taken. If the technology is based on internal development, R&D is usually maintained and carried out by the corporate R&D organization with liaison support into the service organization. If the technology is purchased, the development and application is usually controlled and coordinated by MIS and/or the service organization. In either case, maintenance of the database and diagnostics algorithms must be maintained by the service organization, typically by the technical and logistics support department.

Summary

In summary, the Blumberg in-depth survey of the state of the art and the results of application, implementation, and rollout of problem resolution diagnostics in control help desks and field service clearly shows the promise and potential of on-line remote diagnostics technology (Figure 99-13) in improving the utilization of service force productivity and efficiency, and making more effective use of service resources (people and parts).

Figure 99-11 Expected and actual return on investment from remote diagnostics.

Figure 99-12 Optimum use of TAC and call avoidance.

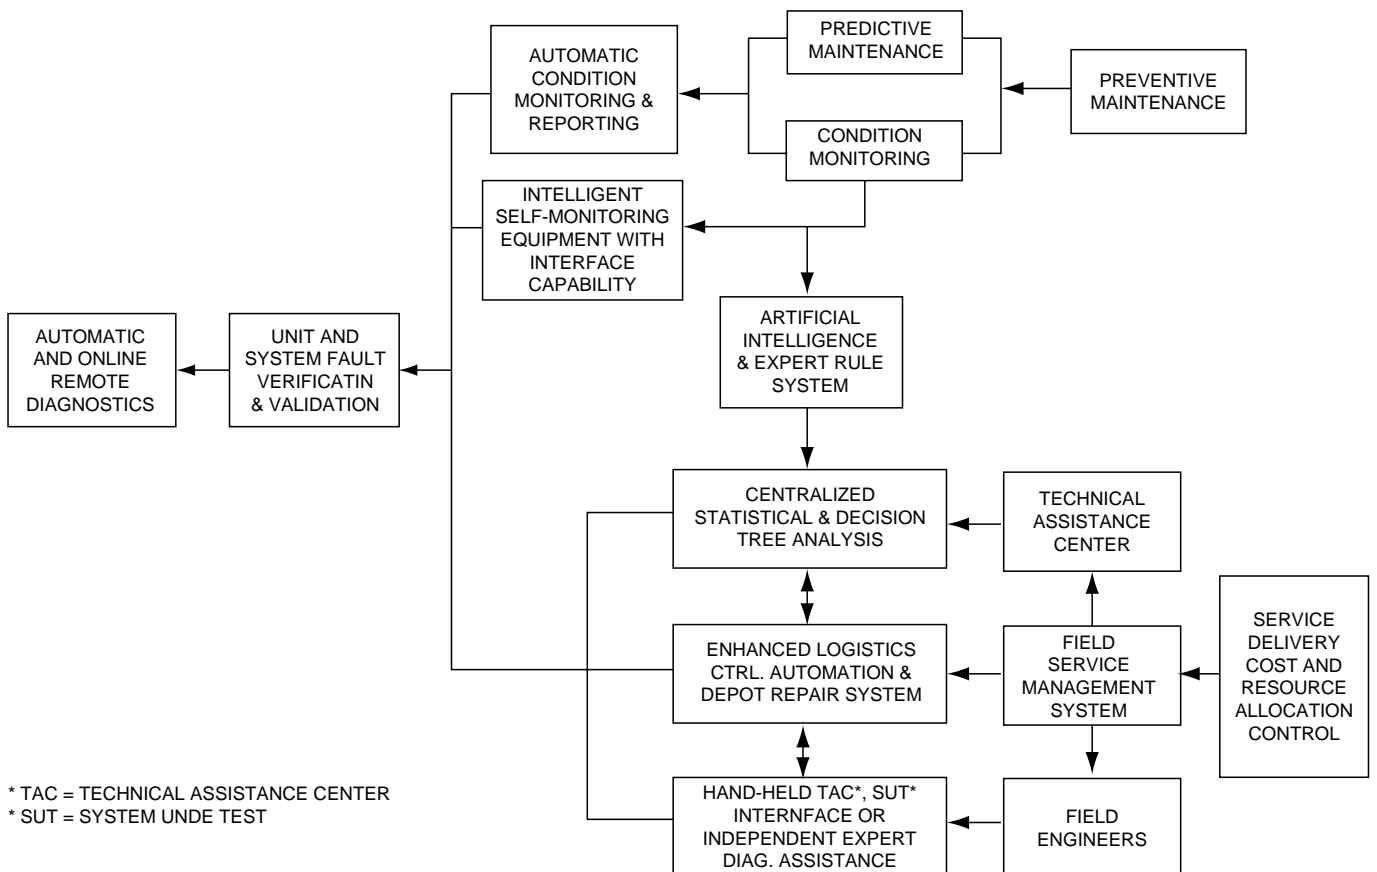

Figure 99-13 Illustrative schematic of automatic online remote diagnostics.

The survey of the current and planned future expenditures for diagnostics used in field service clearly indicates that the overall service diagnostics market is currently sizable, in the range of \$2 billion as of 1997. This current expenditure and growth primarily will occur in the electronics arena, but there is still substantial development and application investments occurring in electromechanical and mechanical areas. The pace of investment will fall off as the service industry shifts from development and experimental research to the application and rollout of standard off-the-shelf technology. Thus, the overall pattern of the diagnostics market indicates a continuing increase in expenditures by the field-service industry for electronics-oriented service diagnostics and some increase with respect to the application and use of this technology in electromechanical and mechanical application areas.

The application and use of diagnostics technology will also be impacted by the ability of the field service management community to recognize the need to search for an optimum (as opposed to a feasible) solution in dispatch, assignment, call screening, call avoidance, and logistics deployment. The further rollout of affordable wireless communications technology such as Ardis and Ram mobile and the new cellular based CPDP technology, coupled with the increased availability of inexpensive wireless based laptop, portables, and CD ROM-based terminals, will increase the ability to provide an array of

powerful tools for diagnostics and repair directly to the service engineer in the field. This ability to augment the diagnostics capability of the service engineer in the field, coupled with the centralized application of artificial intelligence-based remote diagnostics for helpdesk/TAC support that build upon, and make use of, an increasing array of data collected within the integrated field service management system, could result in a significant improvement in the positive impact of problem resolution and diagnostics technology in field service (Figure 99-14). The new, integrated field service management systems provide the basis for automatically collecting problem and symptom data and relating these to the cause and corrective action information. As the availability of accurate and reliable maintainability and repair data increases to meet the data requirements of the diagnostics technology, the scene will be set for further significant improvements in the application and use of diagnostic technology in the field service industry in the 21st century (Figure 99-15). As shown in the above analysis, cost justification of advanced problem resolution and diagnostics technology clearly shows the value of this technology in improving service productivity, efficiency, and profitability.

As the purchase and use of off-the-shelf software and predeveloped knowledge bases prevails over expensive academically and research and development oriented diagnostics applications, this technology will be broadly applied.

Real-Time Executive Dashboards and Virtual Instrumentation: Solutions for Health Care Systems

Eric Rosow

Director of Biomedical Engineering, Hartford Hospital
Hartford, CT

Joseph Adam

President, Premise Development Corporation
Hartford, CT

Successful organizations have the ability to measure and act on key indicators and events in real time. By leveraging the power of virtual instrumentation and open architecture standards, multidimensional executive dashboards can empower health care organizations to make better and faster data-driven decisions. This paper will highlight ways in which user-defined dashboards can connect to hospital information systems (e.g., ADT systems and patient monitoring networks) and utilize Statistical Process Control (SPC) to “visualize” information. The case studies described will illustrate enterprise-wide solutions for:

- Bed management/census control
- Operational management
- Data mining and business intelligence applications

Background

Virtual Instrumentation Revolution

In the last decade, the virtual instrumentation (VI) revolution has empowered engineers to develop customized systems and solutions, in the same way the spreadsheet has empowered business managers to analyze financial data.

Virtual instrumentation can be defined as:

“A layer of software and/or hardware added to a general purpose computer in such a fashion that users can interact with the computer as though it were their own custom-designed traditional electronic instrument.”

Benefits of User-Defined Virtual Instruments

The benefits of virtual instrumentation are increased performance and reduced costs. Because the user controls the technology through software, the flexibility of virtual instrumentation is unmatched by traditional instrumentation. The modular, hierarchical programming environment of virtual instrumentation is inherently reusable and reconfigurable.

Virtual instrumentation applications have encompassed nearly every industry including the telecommunications, automotive, semiconductor, and biomedical industries. In the fields of health care informatics and biomedical engineering, virtual instrumentation has empowered developers and end-users to conceive, develop, and implement a wide variety of research-based biomedical applications and executive information tools.

Case Study #1: A Real-Time Bed Management and Census Control Dashboard

The Challenge

To provide a hospital or an integrated health care delivery network with enabling technology to maximize bed resources, manage varying census levels, reduce emergency department wait times, and avoid patient diversions.

The Solution

The Bed Management/Census Control Dashboard (BMD) is an integrated, easy-to-use application that enables users to access, analyze, and display historical and current patient and bed information easily. This information is continuously updated from the hospital's Admission/Discharge/Transfer (ADT) system. The BMD utilizes real-time monitoring, automation, and communication to achieve a combination of Process Improvement and Decision Support advantages.

• Process Improvement

The BMD enables more efficient patient placement by reducing and eliminating phone calls and paper processes, and automatically matching patient requirements to available resources. Specifically, the system assists with the clinical and business decision processes that occur when a patient needs to be assigned to a specific bed location. Via continual, “real-time” updates across the hospital's network, BMD users are assured that they have accurate data available to them when and where they need it.

Current ADT systems are admissions and billing systems geared toward financials. The BMD complements these systems with clinical requirements and was designed to improve operational efficiencies on a unit and/or hospital-wide. Intuitive modules are used to display and provide alerts on quantitative results in real-time, providing an easy way for personnel to know such details as which beds are available and ready for immediate use, which beds have been requested by other units, or which beds have patients with special requirements.

• Decision Support

The BMD is an easy-to-use Business Intelligence application. It has been designed to allow administrators, clinicians, and managers to easily access, analyze, and display real-time patient and bed availability information from ancillary information systems, databases, and spreadsheets. The dashboard provides on-demand historical, real-time, and predictive reports, alerts and recommendations. Decision-makers can easily move from big-picture analyses to transaction-level details while safely sharing this information throughout the enterprise to derive knowledge and to make timely, data-driven decisions.

An Air Traffic Control Tower for Beds

In many ways, the BMD is similar to an air traffic control tower. Like a real air traffic control tower, this application is real-time and mission-critical. It must handle scheduled and emergency events. The system assists with the clinical and business decision processes that occur when a patient needs to be assigned to a specific bed location. Collectively, this system provides organizations with an array of enabling technologies to:

- Schedule/reserve/request patient bed assignments
- Assign and transfer patients from the emergency department and/or other clinical areas such as intensive care units, medical/surgical units, operating rooms, or post-anesthesia care units.
- Reduce and eliminate dependency on phone calls to communicate patient and bed requirements
- Reduce and eliminate paper processes to manage varying census levels
- Apply Statistical Process Control (SPC) and “Six Sigma” methodologies to manage occupancy and patient diversion
- Provide administrators, managers, and caregivers with accurate and on-demand reports and automatic alerts via pagers, e-mail, phone, and intelligent software agents.

PROBLEM	SOLUTION
ADT systems are not designed to provide sufficient clinical information for appropriate patient placement.	BMD integrates all required information in real-time (e.g., monitor required or negative pressure room).
Lack of accurate bed availability information can result in lost admissions and excessive wait times.	BMD provides the information that is necessary to significantly improve the efficiency of patient placement and discharge.
Inefficient communication while "searching" for the appropriate bed for a patient.	BMD automates the notification process via dashboard, pager, or e-mail.
23+ hour "observation" outpatients that occupy inpatient beds without payer authorization.	BMD has built-in 24 x 7 automated alerts via intelligent agents and pagers.
Difficulty accessing meaningful historical, current, and predictive data.	BMD provides data mining and decision support tools to create useful information from data.

How It Works

The Bed Management Dashboard is accessible via a web browser or via a client application. The supporting architecture of the BMD system is a standard N-tier server-based system, which, depending on the end-users' needs, consists of one or more of the following: A web server, an application server, a database server, and an ADT interface server.

Key information from the hospital's ADT system is automatically fed to the BMD via a Health Level Seven (HL7) data stream. The system also has been designed to accept inputs from patient monitoring and nurse call networks. Figure 100-1 illustrates the flow of information from the ADT system to the user's desktop. The system typically receives up to 12,000 transaction messages per day that are parsed into appropriate data elements by a HL7 parser and are stored on a database server.

The log-in authentication module accesses a hospital's central user-login repository to validate the user's login information. This module enables single-user sign-on (SSO) capability by providing a user with the same username and password used by the other applications that authenticate to the central user log-in repository.

The integrated data mining and report module consists of a number of standard reports that take advantage of the data-warehouse nature of the BMD. These reports include, but are not limited to, historical census report, real-time census report, bed manager report, physician discharge report, and discharge compliance report. In addition, access to the data by

industry standard report writers, such as Crystal Reports and Access give technical users the ability to create complicated or special reports as desired. For example, the BMD offers extensive *ad hoc* reporting capabilities that range from length of stay (LOS) and "Care Day" metrics, to asset management analyses (on beds and patient monitor utilization), to biosurveillance reports that have been requested by state and federal organizations such as the Department of Public Health and the Centers for Disease Control and Prevention.

The utility and configuration module gives system operators the ability to administer BMD users (e.g., add new users and modify new or existing user-security settings); administer service, unit, rooms and beds (e.g., add or modify clinical services, units, rooms, and beds and their inter relationships); define automated alert thresholds; and configure unit floorplan diagrams.

The embedded backup utility module consists of a local version of the bed management database that is constantly updated. Access to this database gives users a self-contained and mobile version of the system that can be used in the event of catastrophic failure of the system hardware or network hardware, or in the event of a crisis that removes the users from direct access to the hospital network.

One of the most important features of the BMD is that it reformats information from the ADT system and presents it to the clinical user in a more "user-friendly" and process-oriented manner. Dynamic and interactive graphical presentations of data are used extensively. Figure 100-2 illustrates how all patients from a given admitting source, such as the Emergency Department, can be displayed and selected from a dynamically sortable "smart table."

Hospital beds are classified as having predefined "attributes," such as being "monitored" or being assigned to the "surgery" service. The needs of patients are similarly described with attributes, such as "monitor required" or "scheduled for surgery." As illustrated in Figure 100-3, the BMD helps to find those available beds in the hospital that meet the specific needs of a patient by guiding the clinical staff through a set of process screens that perform the match.

Decisions for patient placement can be centralized or decentralized. The dashboard allows proper communication between the appropriate parties. Status of decisions is automatically tracked, and a monitoring process can detect and notify key stakeholders of any process delays. Admitting or emergency departments can be notified of automatically decisions, if appropriate. Reporting of information is provided by on-line screen views of data tailored to the needs of a particular class of system user. Unit personnel can view detailed information as well as summary roll-ups of their patients. Figure 100-4 illustrates how patient information can be viewed in a dynamic and interactive floorplan mode.

Administrators and program directors can view data over a wider scope that encompasses multiple units, services, or physicians. An example of a summary report is shown in Figure 100-5.

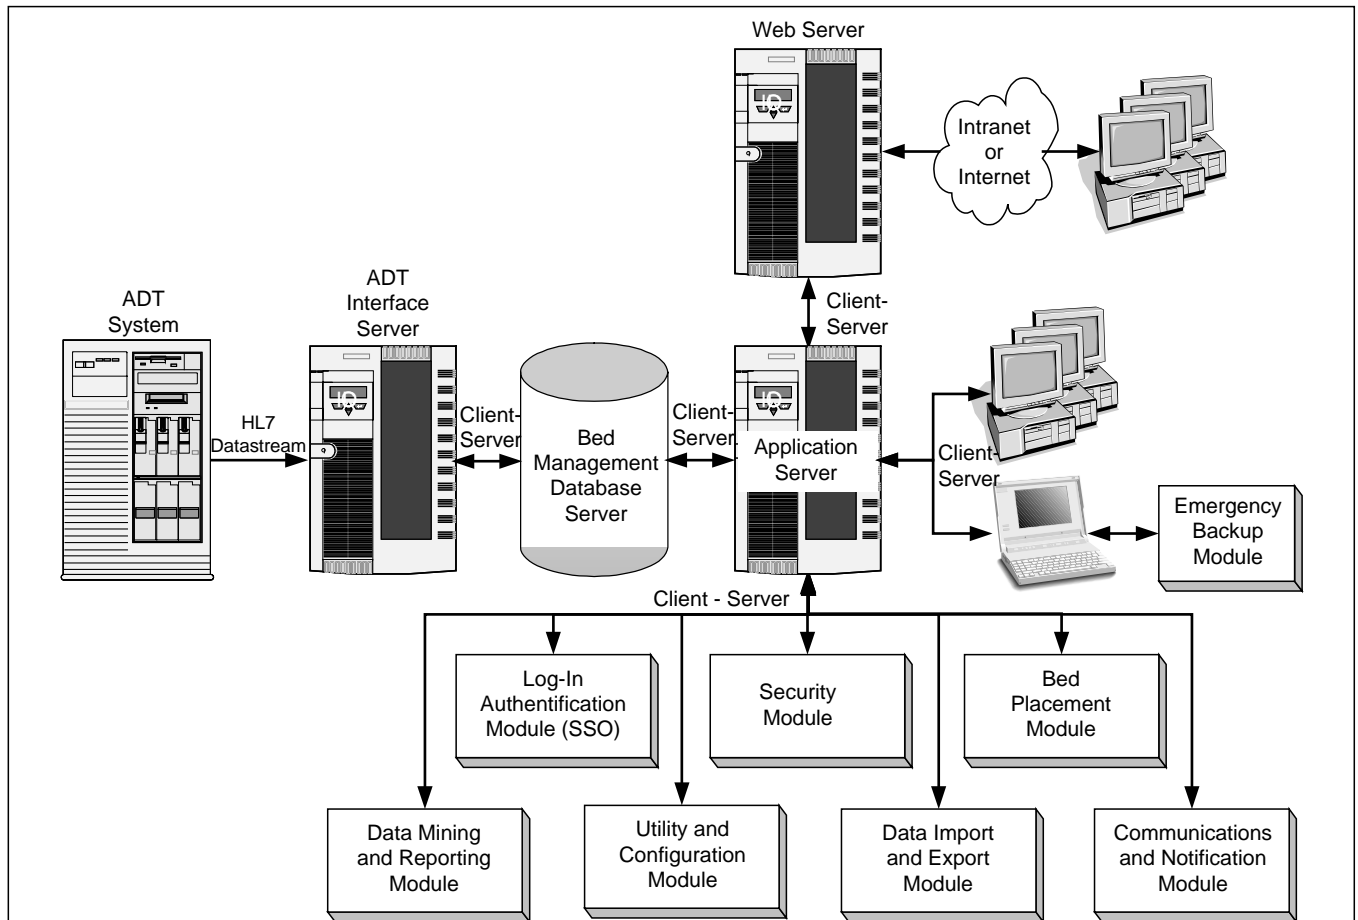

Figure 100-1 System diagram. The BMD consists of four major components: the ADT interface, the database server, an application server, and a web server. The system has been designed to interface with any ADT system that provides an HL7 interface and utilizes TCP/IP as a communication protocol.

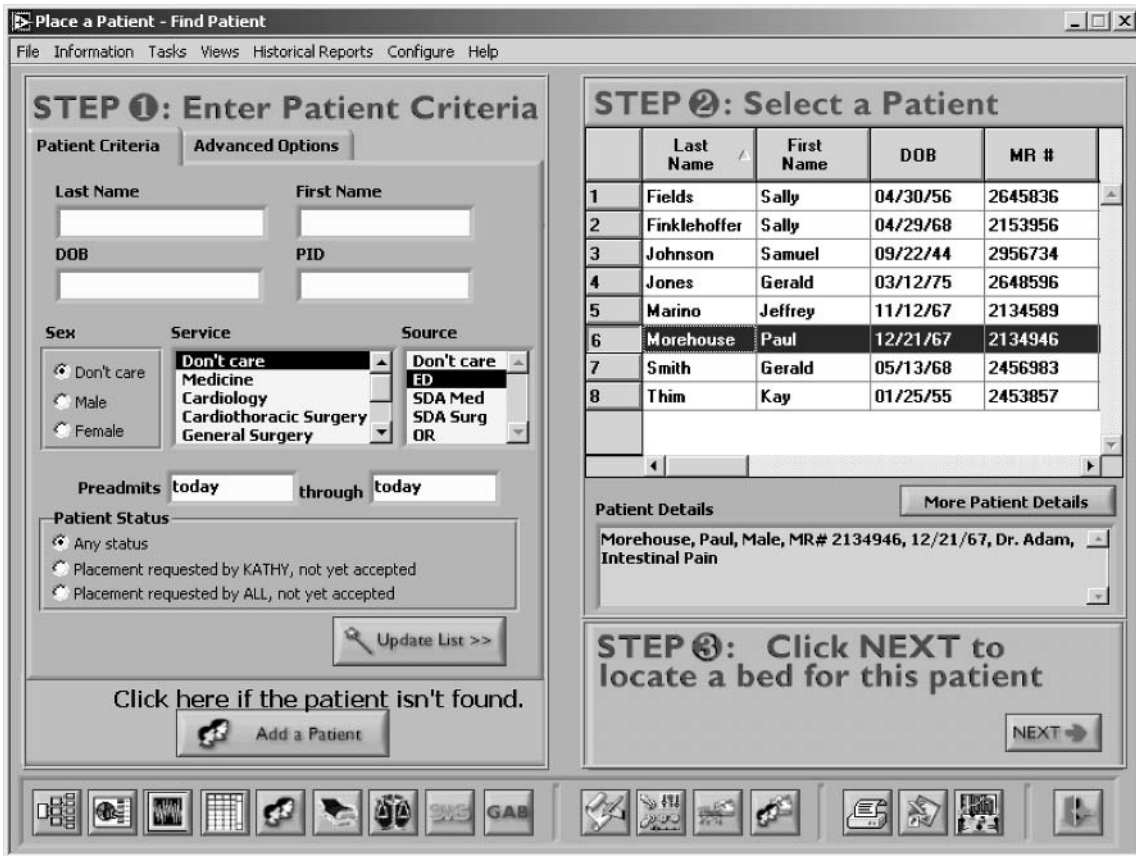

Figure 100-2 Find Patient. This screen is primarily used to request a bed for a patient. The user first enters various criteria to identify the patient. The system then displays all of the patients who meet the specified criteria. Finally, the user selects the patient in question and presses "NEXT" to move to another screen, where an available bed is located and requested.

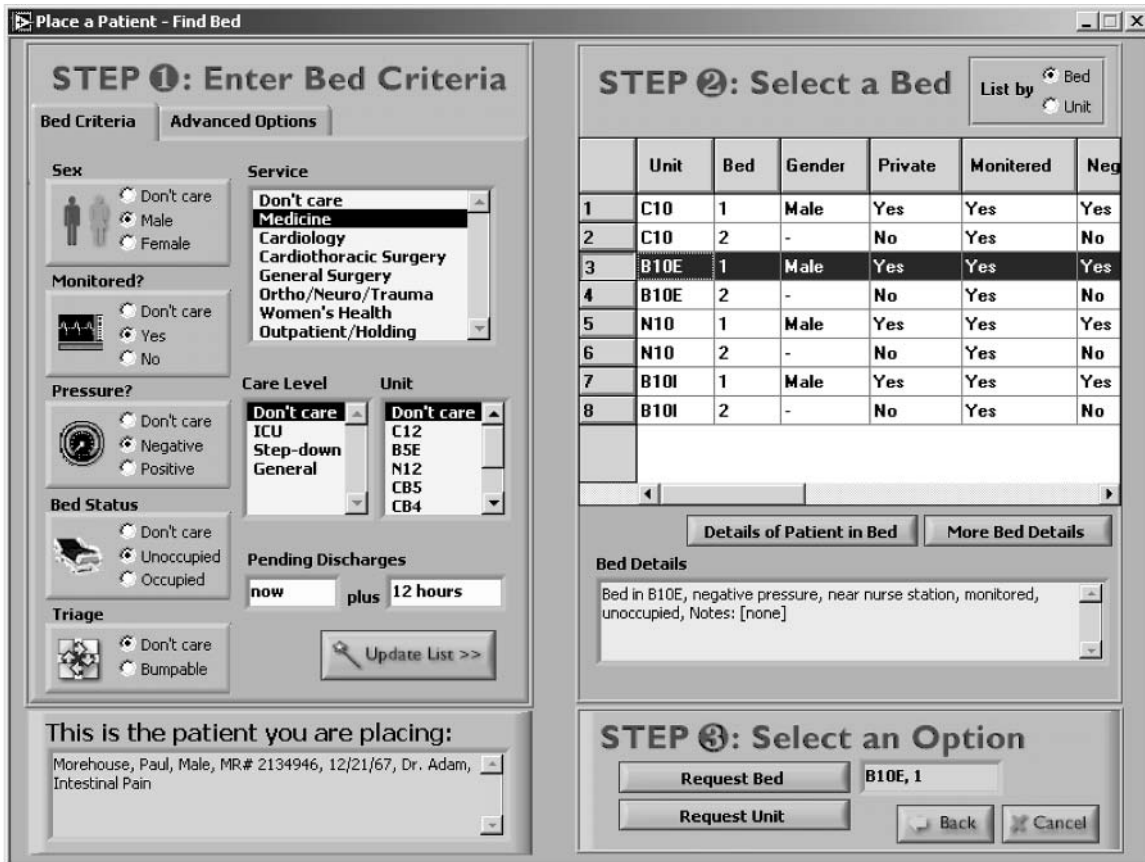

Figure 100-3 Find Bed. Once a patient is selected, this "Find Bed" screen is used to locate a specific bed or unit for the patient. The user first enters various criteria about the type of bed that is needed (e.g., patient gender, monitor required, or negative pressure room required.). The system then displays all of the available beds that meet the specified criteria. Finally, the user selects a particular bed or unit for the previously specified patient.

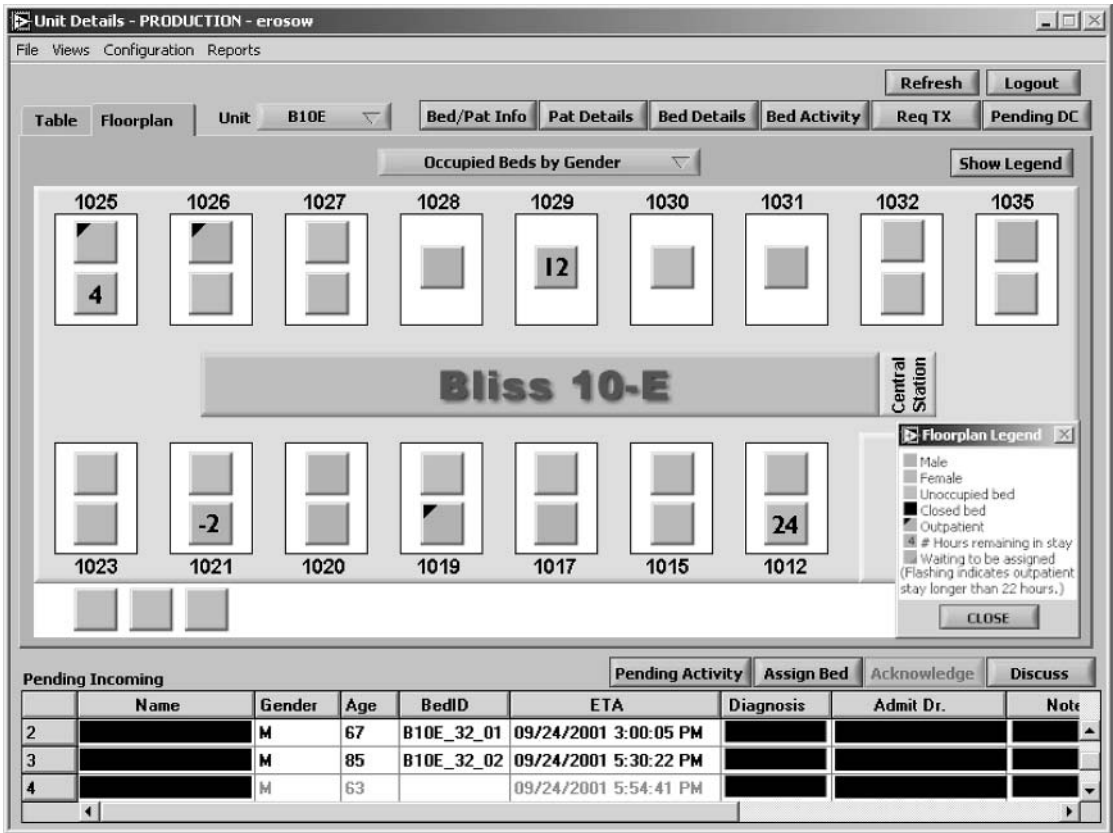

Figure 100-4 Unit Details (Floorplan view). This screen provides a graphical view of an intensive care unit. Each bed is presented as a square using a simplified floorplan view. Colors are used to indicate the selected attribute of the patient or bed. For example, the above screen indicates available beds in green, and occupied beds in red. The gray beds (flashing) are those with pending discharges, and the black bed is closed/inactive. Many other color-coded options are available via the pull-down selector. These include patient and bed attributes such as gender, monitored bed, negative pressure room, and service (e.g., cardiology, surgery, and orthopedics).

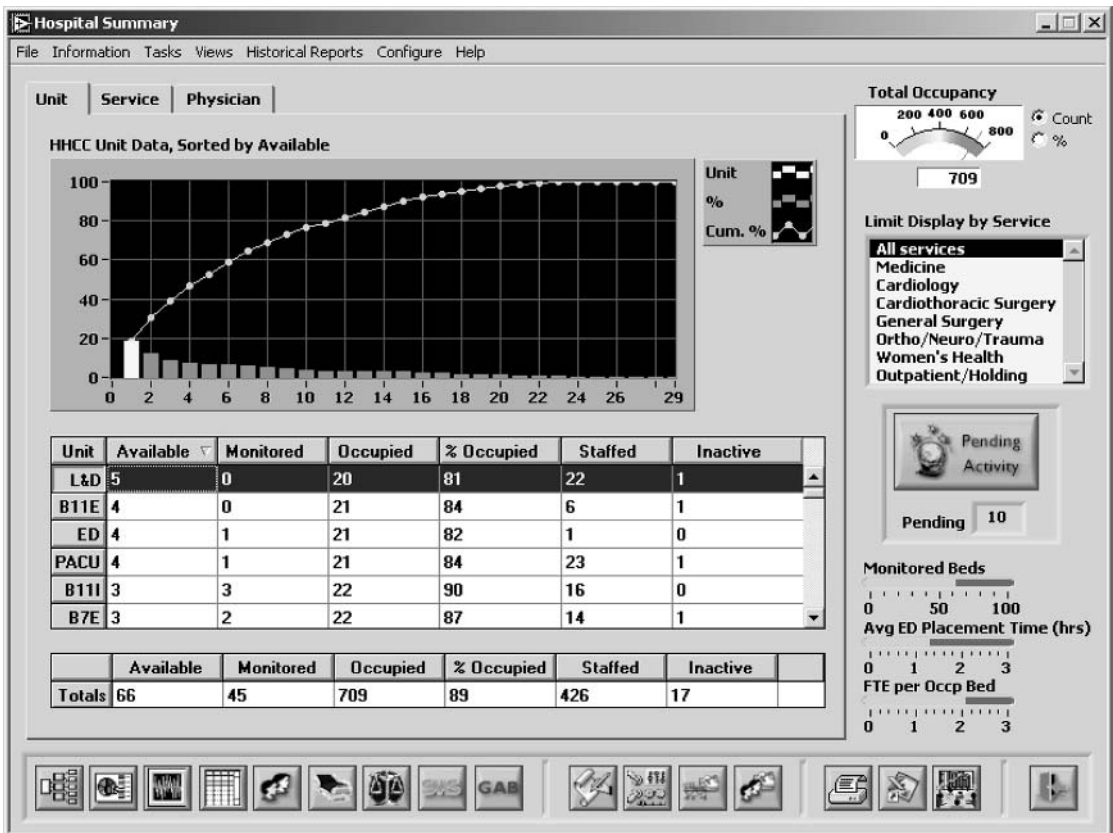

Figure 100-5 Hospital Summary. This screen is used primarily by administrators who need to see a global view of the hospital status. Table and Pareto charts profile the various units and the current status summaries of each unit. These patients also can be rolled up into services, or grouped by physician. In addition, patients can be aggregated in many other ways such as time of admission, length of stay, and admitting diagnosis.

One key feature of this system is its use of "Intelligent Agents." These online agents, as shown in Figure 100-6, are constantly monitoring and analyzing patient and census information, and they have the ability to detect key system situations, such as high census in a unit (i.e., no available beds), excessive ED placement time for a particular patient, or delays in responses to placement requests.

Patient Confidentiality

A full security system is embedded within the dashboard to audit user access and to assign users to definable system roles. These roles are restricted to specified processes and are prohibited from viewing or changing certain data. The system is designed to be fully compliant with the evolving Health Insurance Portability and Accountability Act (HIPAA) regulations.

Case Study #2: PIVIT – Performance Indicator Virtual Instrument Toolkit

The Challenge

Managing multiple data sets and performance indicators can be tedious and time-consuming. This results in a compromised ability to assess effectiveness, detect problems, and capitalize on opportunities for improvement.

The Solution

An easy-to-use dashboard (PIVIT) was developed to integrate disparate data sets and performance indicators to monitor operational performance and to identify areas for performance improvement.

System Overview

PIVIT is an acronym for "Performance Indicator Virtual Instrument Toolkit" and is an easy-to-use data acquisition, analysis, and presentation application. PIVIT applies virtual instrument technology to access, analyze, and forecast clinical, operational, and

financial performance indicators. Examples include applications that profile institutional indicators (e.g., patient days, discharges, percent occupancy, ALOS, revenues, and expenses) and departmental indicators (e.g., salary, non-salary, total expenses, expense per equivalent discharge, and DRGs). Other applications of PIVIT include 360-degree peer review, customer satisfaction profiling, and medical equipment asset management.

PIVIT can access data from multiple data sources. Virtually any parameter can be easily accessed and displayed from standard spreadsheet and database applications (e.g., Microsoft Access, Excel, Sybase, and Oracle) using Microsoft's Open Database Connectivity (ODBC) technology. Furthermore, multiple parameters can be profiled and compared in real-time with any other parameter via interactive polar plots and three-dimensional displays. In addition to real-time profiling, other analyses such as statistical process control (SPC) can be employed to view large data sets in a graphical format. Statistical process control has been applied successfully for decades to help companies reduce variability in manufacturing processes. These SPC tools range from Pareto graphs to Run and Control charts, to process capability distributions.

Statistical process control has enormous applications throughout health care. For example, Figure 100-7 is an example of how Pareto analysis has been applied to a sample trauma database of over 12,000 records. The Pareto chart can display frequency or percentage, depending on front-panel selection, and the user can select from a variety of different parameters by clicking on the "pull-down" menu. This menu can be configured to automatically display each database field directly from the database. In this example, multiple fields (e.g., e-code, DRG, principal diagnosis, town, zip code, and payer) can be selected for Pareto analysis. Figure 100-8 further illustrates some of these custom virtual instruments that apply statistical process control to a variety of data sets.

Figure 100-9 shows how equipment selection filters allow the user to restrict data analysis to desired equipment and equipment parameters (e.g., device category, manufacturer, status date, locations, or models). Figure 100-10 illustrates the equipment statistics module that allows users to graphically profile CMMS data in the form of a histogram or a Pareto chart. In this example, the devices are sorted and plotted in a Pareto chart. By clicking on any of the column headings or selecting a different option from the pull-down menu, the graph will dynamically update. Detailed data are rolled up to summary levels and can be drilled down to fine detail, all with a few clicks of the mouse. Users do not need to know how to write queries or program code. The equipment history profile in Figure 100-11 allows users to visualize relationships of work order events for a specific device, as they occur in time. Each vertical line or cursor represents a specific activity (e.g., incoming inspection, preventive maintenance, unscheduled repair, or user error).

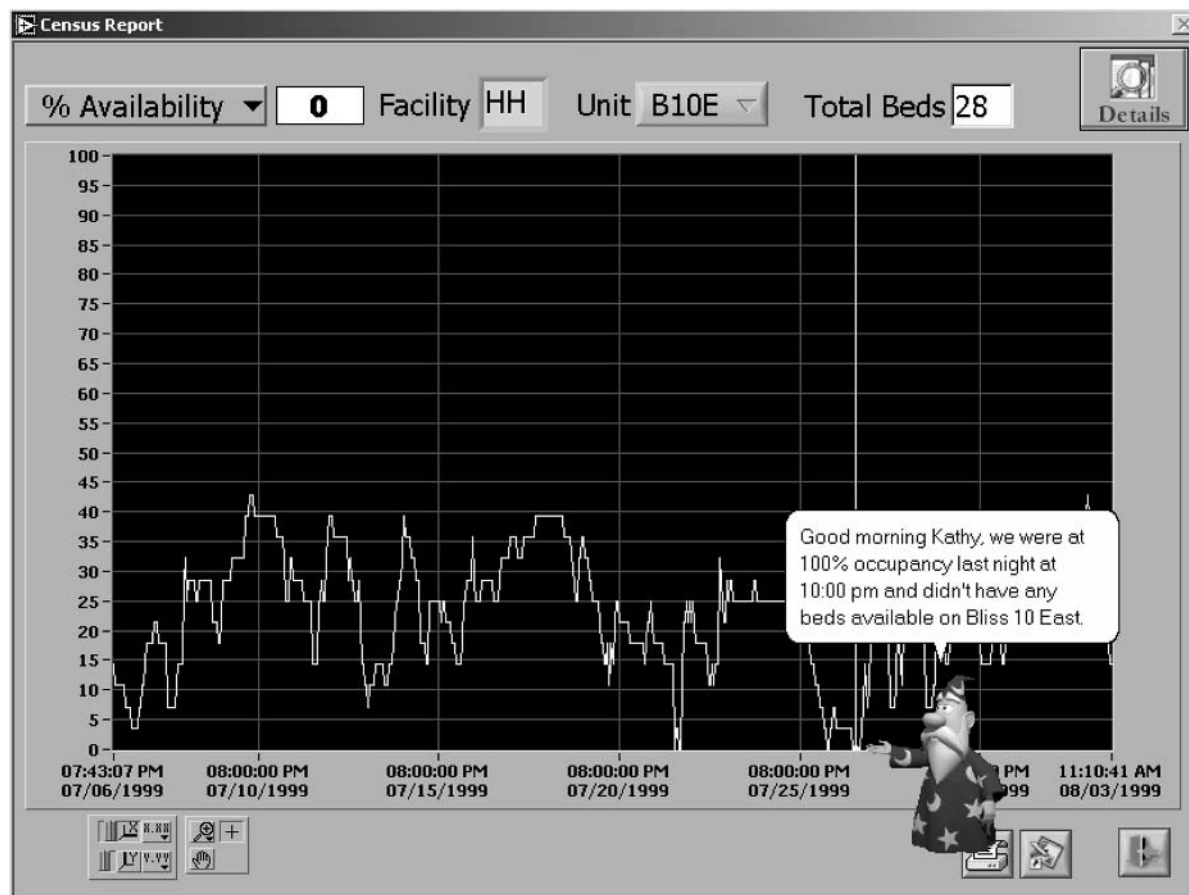

Figure 100-6 Intelligent agents. The BMD can also employ on-line "intelligent agents" to provide assistance and alert the user of important alarm conditions that otherwise might have gone unnoticed. Messages can be in the form of an onscreen agent (such as Merlin the Wizard) or also via e-mail, pager, fax, and/or telephone.

Conclusion

Executive dashboards and virtual instrumentation allow organizations to effectively harness the power of the PC to access, analyze, and share information throughout the enterprise. The case studies discussed here illustrate ways in which various institutions have conceived and developed “user-defined” solutions to meet specific requirements within the health care and insurance industries. These dashboards support general oper-

ations, help hospitals to manage fluctuating patient census and bed availability, and enable insurance companies to identify best practice patterns, accurately price products, and increase market share. Decision-makers can move easily from big-picture analyses to transaction-level details while safely sharing this information throughout the enterprise to derive knowledge and to make timely, data-driven decisions. Collectively, these integrated applications directly benefit health care providers, payers, and, most importantly, patients.

Telemedicine: Clinical and Operational Issues

Yadin David

Director, Center for TeleHealth and Biomedical Engineering
Department, Texas Children's Hospital
Houston, TX

In a remote village in Central America, an otherwise unmanaged child's infection could have taken a turn for worse, had it not been for the long distance diagnosis capacity brought about by the recently installed telemedicine system among Zacapa, Guatemala, and Houston, Texas, where subspecialists in the field of Pediatric Dermatology viewed the wound and prescribed the critically needed treatment. Recent developments in the telecommunications and the information technology fields hold the promise of improved access to, and the better utilization of, health care-related resources. In addition to these developments, the deployment of interactive distant training programs offers an opportunity to decrease the knowledge gap between the leading academic medical centers, where new medical knowledge is continuously being discovered, and the remote health care practitioners who find themselves pressed to deliver quality care that meets the needs of their communities in a competitive environment of limited resources. Telemedicine is creating new opportunities for imagining the possibility of a more efficient and accessible health care delivery system. Telemedicine is merely the tool (not the end) by which to negotiate and overcome barriers on the road to the delivery of quality services that the present system cannot deliver as effectively. The developments of modern telecommunications and information technology tools present a radical opportunity to change the health care delivery infrastructure from the ground up. The implementation of telehealth programs in such an environment is supported by enthusiastic approaches, but not with enough planning tools. There is a need to understand how to best adopt the advantages offered through intelligent communication that limitlessly extends the boundary of our senses, records, activities, and outreach. At its basic application, telemedicine can take the distance out of caring. Clinical needs, including the provision for innovative quality continuing education, is one of the programs' prime focuses. However, once moved beyond the clinic, the financial, legal, and engineering implications of telemedicine challenge the *status quo*. If telemedicine is going to become a staple of medical practice on our planet, a massive re-engineering of the national and international telecommunications infrastructure, reimbursement legislation, and clinical practices will be required. There are over 150 telemedicine programs in operation today. It is estimated that 60% of them are less than six years old (Peredni, 2000), representing a relatively new modality in the health care delivery system, where the vast majority of the providers are still debating the appropriate entry course and the following regulatory and sustainability issues. This chapter reviews the evolution and the major issues to consider before embarking on a telemedicine program.

Same Problems: Different Solution

The Center for TeleHealth (CTH), one of the first telemedicine programs to focus solely on the extension of pediatrics subspecialty services, is the result of a collaborative program between the Texas Children's Hospital and the Baylor College of Medicine. While the Center was created for the specific goal of linking the institutions' expertise to remote communities in Texas as well as globally, it would not have enjoyed the executive and medical faculty's support if it had not been for the success demonstrated during its initial applications, the result of using video engineering concepts to solving intrahospital problems. It required the installation of a video network for the transmission of real-time information transmission of echocardiography to the locations where the experts were available (i.e., the cardiology reading area). Soon, other problems were solved with a similar measure of success. The subspecialty coverage of a remote clinical area, the newborn nursery, successfully tested the provision of remote video monitoring of babies by neonatologists (Adcock et al, 1999). While new knowledge is being discovered and acquired at an accelerated pace, specifically in the field of diagnostic and therapeutic medicine, within the major cluster of the academic medical centers the care provider (who practices in the remote and, at times, rural area, or in the overburdened urban clinics) has yet to realize how best to absorb and deploy this new information. Telehealth is providing a unique opportunity to restructure the dissemination of knowledge methodology used in today's health care delivery system in a way that will distribute specific competencies to the most needed environment—the best practice at the point of care. This focus will allow our society to move from a reactive mode of delivering

care toward a life-long health management where individual accountability, preventive medicine, and customized wellness programs are integral components of a new health management methodology.

The Telemedicine Evolution

Telemedicine is not a new entity. It has enjoyed over seventy years of historical evolution. The April 1924 issue of the *Radio News Magazine* showed a drawing of a physician viewing a patient over short-wave radio set that included a television-like display. More realistically, the early programs in the 1950s and 1960s were highlighted with some success by the Nebraska Psychiatric In-state and the Massachusetts General Hospital and Boston's Logan International Airport link (Dakins, 1997). However, these programs lacked the ability to deliver sustained satisfaction to the health care providers or to the patients involved. Following the invention of the color television and launching of satellites in 1965, Dr. Michael DeBakey, the cardiovascular surgeon at the Baylor College of Medicine, started to incorporate video tools into the medical training program. That year, he successfully broadcast the first live cardiac surgery, from the operating rooms at the Methodist Hospital at the Texas Medical Center to Europe, utilizing satellite transmission. Colleagues in Amsterdam viewed and heard Dr. DeBakey mentoring the procedure at the time a new technique for teaching cardiac surgical intervention. The investment by the United States government in the late 1980s and early 1990s in the integration of better telemedicine tools placed a focus on the rural communities and the need to extend care to the internationally deployed military forces. These efforts provided the initial impetus for today's telemedicine programs. The new modality, the Internet, provided another example of ways in which the barrier of distance can be overcome by having access to tools that enjoy a much more ubiquitous communications platform to transmit information between any two distant locations at anytime. In 1983, the first use of the Internet to disseminate medical information between participants took place at the Texas Medical Center and demonstrated the potential for scientific interactions that had been untried before then. Along with the use of satellites and telephone lines to deliver medical information, the Internet now provides communication between two single points, as well as the ability to share information among multiple sites simultaneously, at an affordable cost. The early applications of video engineering were, essentially, an attempt to overcome intrahospital information-flow "bottlenecks." The connection with remote rural communities was not attempted until sufficient experience had accumulated with intra-hospital transmission of video, with the available telecommunications services including the "last mile," the point between the shared infrastructure and user connectivity. Thus, the Texas Children's Hospital/Baylor College of Medicine Medical Center program began in 1993 to take advantage of these opportunities to reach out with its educational and clinical programs beyond the confines of the Center, reaching out 400 miles southwest of Houston to McAllen, Texas, near the Mexican border. The program then, as today, focused on the extension of pediatric subspecialty expertise to communities in need. The growing acceptance of telemedical-based services is changing the way health care is delivered and provides opportunities that had not been available before. In a recent survey of telemedicine service providers conducted by *Telemedicine Journal*, almost 70% of the responders cited the need to increase access to specialty care as the major motivation for initiating remote interactive clinical service while 33% of the responders cited cost saving as the primary methodology for measuring the success of such a service (Field J, 1996). While the service can be administered in a variety of platforms, the needs to accommodate clinical requirements and to appreciate technological limitations are universal. However, these requirements and limitations change from one program to another and from one location to another. Successful development and implementation of telemedicine service is dependent upon the ability to focus on and address specific clinical needs, the integration of infrastructure with existing platforms, and the availability of a reliable and sufficient end-to-end broadband telecommunications service. In addition, sensitivity to cultural preferences and compliance with legal issues has an impact on performance as well.

The Telemedicine System

Interactive computers and advanced telecommunications technologies are transforming every aspect of our life. Medicine is no exception. From virtual classrooms to simulation research, and from pharmaceutical dispensers to artificial organ replacements, advances are generating breakthrough applications that improve the quality of life for an ever-increasing number of people. Health care providers and educators as constituents of this transformation era enjoy new opportunities created for their active participation in this transformation. Reviewing the positive impact that the integration of ostensibly independent patient care services has on the efficient management of the total quality of care, of education, and of collaborative research, it is not surprising that telehealth deployment is on the rise. The forces that drive this phenomenon include the following:

- The need to manage the entire disease encounter
- The desire to apply standard quality of care over a wide geographically distributed community
- The escalation of customer expectations
- Globalization of health care and its support services
- An increase in patient and provider convenience
- User acceptance of the current technological competency

Telehealth can be envisioned as the practice of health care delivery through the use of advanced communication technologies, computers, video instrumentation, and medical devices to exchange information and to deliver services that overcome the barriers of distance, time, and socio-cultural differences. Specific applications include the following:

- Delivering medical services
- Consultation or validation
- Prevention
- Diagnosis,
- Treatment
- Transferring medical data
- Education
- Collaborative research

Current applications are classified as follows:

1. Initial screening/evaluation of patients
2. Triage decisions and pretransfer screenings
3. Medical and surgical follow-up and medication review
4. Consultation for primary care encounters
5. Real-time subspecialty care consultation and planning
6. Management of chronic diseases and conditions
7. Extended diagnostic work-ups
8. Review of diagnostic images
9. Preventive medicine and patient education

In addition, the Medical Center has successfully conducted real-time interactive clinical engineering seminars between Houston, Texas and Riyadh, Saudi Arabia. Many other examples, such as the Visions of Health and Peace project, through the use of telemedical tools, demonstrated the promise of global biomedical partnership between Israel and the United States. This is a critical opportunity for engineers to participate in supporting telemedicine programs by demonstrating skill sets that can assert and establish the quantifiable level of service that ensures an appropriate match between the fidelity of acquiring and delivering sound and video levels and the clinical requirements of the specific encounter and that can service and support the operations of this complex system.

The Telemedicine Practice

Telemedicine is the use of electronic information and communication technologies to provide and support health care services when distance and time separate the participants (Field MJ, 1996). In its simplest form, a telemedicine program consists of a site where a consulting physician is located (the "hub") and a remote location (the "spoke") where the referring physician and the patient are present. The consultation between the two peers can take the form of a diagnosis session or a second opinion session. The central hub can serve one or many spokes located at remote sites. The peer-to-peer review can be practiced in two different modalities—in real-time or in delayed time known as the "store-and-forward" mode. The difference between the modalities is the time span associated with the consultation protocol and the requirements of bandwidth.

Telemedicine practices can be categorized into variety of modalities, for example, according to type of services provided. Telemedical encounters can focus on clinical, educational or administrative programs. A program that provides clinical encounters must comply with a variety of regulatory guidelines and must adhere to policies and procedures that are quite different from those required for the provision of educational services. Another categorization can be along the types or the size of network deployed, such as a point-to-point or a hub-and-multiple-spokes system. However, the most popular categorization is done along the span of time within which the telemedical encounter begins, is reviewed, and completed.

Most of the telemedicine programs operate in a synchronous mode, or in what is known as an interactive real-time full-motion encounter. The other modality, store-and-

forward, is an asynchronous mode whereby the referring physician and the patient do not have to be present at the time of the consultation together with the specialist. Rather, the referring physician gathers the patient information over a period of time utilizing a battery of diagnostic instruments, ranging from electronic stethoscope and X-ray images to pathological slides or cine fluoroscopy as shown in Figure 101-1. Other patient information, such as echocardiograms, can be incorporated, as can dictation of patient symptoms, family history, vital signs and demographics. This information is then packaged and moved as a completed file, electronic portfolio of the patient, to the consulting physician address at the hub. The transmission is encrypted to protect privacy and to provide confidentiality of information. The consulting physician, after being alerted to the arrival of new electronic file, will open the portfolio, review it, and then render a diagnosis and an opinion as to the management of this condition. The consultant will send it back to the referring physician for action. There are several advantages to the store-and-forward modality. The patient need not be constrained by the schedules of the referring and the consulting physicians; the cost of telecommunications is minimal. On the other hand, the advantage of the real-time interactive mode is the high presentation quality that can be deployed, and the ability to have multiple subspecialists participating simultaneously in management of the condition permits earlier and quicker decision making processes. Accompanying the increase in clinical applications, the appreciation for the minimum features level and fidelity provided by the various types of equipment and communication systems must become clearer in order to efficiently match capability with service needs.

There is a critical opportunity for engineers and clinicians to participate in this process by defining the appropriate fidelity level that will best accommodate the clinical requirement. There still are critical financial, legal, and technical barriers to overcome. These include the following:

- Reimbursement
- Professional component
- Administrative component
- Technical component
- Liability
- Licensure
- Scheduling issues
- Equality/universality of care
- Patient/MD relationship
- Appropriateness of application
- Patient resistance
- Abuse/over-utilization
- Confidentiality/privacy

Transmission Test Conditions

The evaluation of room-based telemedicine systems requires the commitment of many resources. There is a continual need to evaluate new, evolving systems and technologies for an optimal match between patient and physician needs and technological capability in order to reach display-fidelity optimization and to refine and standardize efforts. The Medical Center test was subjective in that its panel of experts was scoring competitors based on their impression and perception of "quality." Seven years ago, it conducted an evaluation test to determine the magnitude of variation in video processing between the systems. The testing protocol provided for a single video source to simultaneously broadcast its signal into two video conferencing systems. The videoconferencing systems were designed to communicate with the video source at different bandwidths. The communication with video source was in real time over a protocol H.320 full T1 carrier service (1.544 Mbps) down to a 1/4 T1 (386Kbps). The video source was changed from an ultrasound examination of a patient cardiac condition to a simulated patient with advanced Parkinson's disease. Other rapid and sudden movements against a large, white background (such as a downhill skiing race) were used as well. A panel of senior medical subspecialists observed the presentations and related their ability to render a medical opinion based on the quality of the displayed video and the fidelity of the audio (Figure 101-2).

For a slow-moving event, such as an examination of skin conditions, a fraction of a T1 line was acceptable for rendering an opinion. However, for ultrasound examination and downhill skiing, the panel opinion was that only presentation-quality 1/2 T1 or better was sufficient to determined minute changes in the conditions presented. Proper lighting and the positioning of the camera during patient examination were also noted as critical for successful assessment of clinical conditions. Finally, the resolution and the overall size of the video screen were determined to have impact on the clinical acceptance of the telemedical encounter as well. The closer the display area was to a real-life size, the more the panel felt it was acceptable.

Consequently, the Center conducted telemedical encounters where content included significant motion through only 1/2 T1 or better and employed the diagonal measure of 31-inch television sets (Figure 101-3). All video sources were calibrated as to level and were connected via a 1X8-video switcher (selector). This enabled the selection of the various sources utilized in the evaluation at the request of the panel members. The output of the selector was passed to a distribution amplifier (D/A) to compensate for losses resulting from the division of the video signals into two paths. The video signals were then passed to the two transmissions CODECs, (Compressor/DECompressor) "A" and "B." Equal lengths of transmission lines connected the CODECs at the "near end" used for analog-to-digital conversion and subsequent compression and transmission of the signals to the CODECs at the "far end" used for reception, decompression, and digital-to-analog conversion. The output analog information from the two "far end" CODECs were connected to individual multisync monitors ("A" and "B"). The monitors, which were both of the same manufacturer and model, had been calibrated prior to the evaluation, using an NTSC laboratory-grade color-bar generator and photometric color tem-

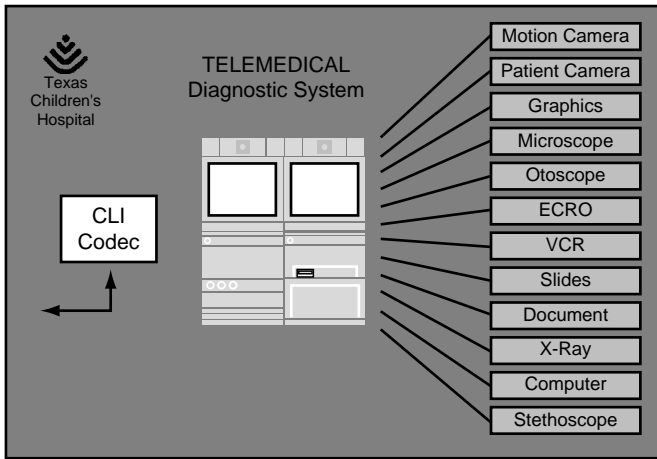

Figure 101-1 Patient information gathered from a battery of diagnostic instruments.

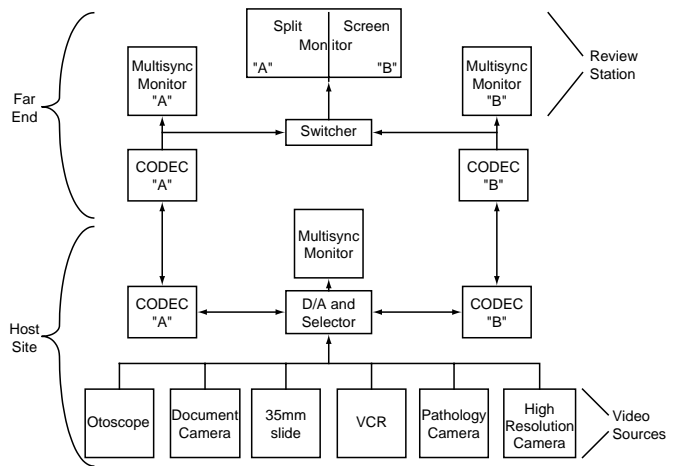

Figure 101-3 Telemedicine evaluation test.

Figure 101-2 Panel of senior medical subspecialists observing and evaluating telemetry presentations.

perature and luminance meters. This calibration ensured that both monitors were objectively as similar as possible in terms of picture quality. In addition, to provide a better side-by-side comparison of the two systems under evaluation, a split-screen monitor was employed. Video information from both CODEC sources was split and sent through a switcher, enabling the side-by-side viewing of video information on a single monitor. Immediately prior to the tests and evaluation, the clinical engineer in charge ensured the integrity of the “double blind” nature of the evaluation by making the final connections from the outputs of CODECs “A” and “B” to the monitor chain. This information was kept confidential until the evaluations were completed.

Resolution of these issues will extend the ability to exchange information and to increase interoperability with legacy systems. This will extend the capacity to engage in this evolution and to determine when it presents sufficient fidelity to deploy this service in the clinical setting. Finally, the legal and regulatory aspects, in addition to the domestic and global aspects, for the test described above must be reviewed.

The Telecommunications Component

Telecommunications, one of the most quickly changing fields, is enabling existing and new platforms to exchange information and to support interaction through unique applications including the medical peripherals. Thus, the management of a telemedicine program must incorporate the understanding of telecommunications technologies and the optimization of this component. The convergence of the digital and the analog transmission methods and the advantages of the various networking technologies require an ability to evaluate and match the network needs with the capabilities of the available infrastructure. Clinical requirements must be matched with technical capacity and supported by financial sustainability to influence the design and the implementation decisions when selecting the platform to be employed. The many modes of communications support speed and bandwidth that ranges from the narrowband used for the traditional telephone

system to the wideband application supported by an integrated services digital network and satellite communications. Various selectable bandwidths and availability and level of service should be considered. In selecting the telecommunications technology, one must clearly know how the network will be designed, what protocols are expected to be used, how much and how often data will be transmitted, and, finally, what the budget will allow for this program.

Video compression, a coding technique that is used to reduce the bandwidth required for the transmission of video images, is a developing science. Recent developments are awaiting validation of its clinical acceptance and are still largely unsubstantiated by a conclusive body of research. Opinions vary widely on the topic, but few hard data exist. The science of visual perception is unique in that it is a subjective function of the brain as well as the eye. No two individuals perceive a particular image in exactly the same way. The threshold of persistence of vision and the measurable speed at which a motion-picture or video screen ceases to flicker and begins to “move” may vary significantly among different observers under different lighting conditions. The eye and brain are thought to retain a visual impression for approximately 1/30th of a second. When viewed as a continuum, this collective retention is “seen” by the viewer as uninterrupted motion. It is important, therefore, that the effect of the compression technique chosen for a telemedicine system will not further modify the assessment of the medical conditions being viewed.

Summary

Telemedicine is an emerging industry with the potential to revolutionize the delivery of care to the benefit of health care systems, providers, and patients. The application of electronically connected parties in the provision of medical care and training has already begun to show some very exciting possibilities. The expansion of telehealth systems will deliver services to the benefit of providers’ networks, the economy, and patients. Recent developments and improvements in standards in the telecommunications and information technology fields hold the promise of improved access to, and better utilization of, health care-related resources. Telemedical services can be deployed in a variety of platforms. Those platforms keep improving the capturing, transmission, and presentation of medical information. The deployment of any one platform, or a combination of several platforms, is dependent on such conditions as clinical needs, level of staffing training, legal and cultural constraints, limited telecommunications infrastructure, regional economics, and the stage of technological development. Therefore, some applications are better suited than others to support the needs of distant health care providers. Telemedicine systems must be tailored to the needs of the participating health care system. Usually, a tiered approach consisting of a mixture of real-time and store-and-forward technologies, wide bandwidth, and low frame rate is the optimal solution. With proper planning and the anticipated advances in computing power, direct medical digital imaging and telecommunications will continue to increase the cost-effectiveness and will expand the scope of telemedicine services. Two modalities of practice are emerging: The real-time interactive mode and the store-and-forward mode. The combination of these modalities with the capabilities to exchange medical information as supported by the new telecommunications infrastructures places telemedicine at a central position for improving access to quality health care by all. Financial, legislative, and regulatory penalties (Center for Telemedicine Law, 2004) must continue to be removed in order to permit everyone in need to reach their goal by finding the ramp and to get onto the telemedicine highway. The contribution of this transformation to the betterment of health for all must be identified and quantified. This challenge is the next and biggest obstacle for the field of telehealth. Dr. Michael DeBakey put it best: “These technologies will allow us to improve the standards of health care around the world ... providing an important opportunity for distant learning and for the dissemination of medical knowledge and support of this goal.”

Picture Archiving and Communication Systems (PACS)

Ted Cohen

Manager, Clinical Engineering Department,
Sacramento Medical Center, University of California,
Sacramento, CA

A picture archiving and communication systems (PACS) is a system that electronically processes, stores, distributes, and retrieves digital medical images in a portion of, or throughout, a health care enterprise. PACS is most commonly used in radiology departments to process and route radiographs and other diagnostic imaging modalities including MRIs, CTs, nuclear medicine scans, and ultrasound images. PACS epitomizes the integration of medical, computer, and communication technologies with its requirements for large amounts of storage, sophisticated databases, large bandwidth, high-speed networks, computational power at the desktop, ease of use requirements for a variety of end-users, and specialized medical application software. PACS can also be used to store image information from cardiac catheterization procedures, endoscopy, dermatology, radiation oncology, echocardiology, and pathology.

One goal of PACS is to improve the imaging department workflow as compared to film-based technologies. PACS automates and, to varying degrees, improves the workflow among imaging modalities, image acquisition, image processing, image distribution and storage, and the associated personnel within the health care institution. Because 70% of the typical radiology department's workload is plain film images, as radiology departments convert to digital modalities, PACS implementation on a larger scale becomes more practical. In addition, the practical implementation of PACS requires high integration with the Radiology Information System (RIS) and/or the Hospital Information System (HIS) for scheduling, workload management, and radiology reports. PACS also may help to alleviate film, film processing, and film storage costs and to reduce the number of retakes and lost films. The growth of high-bandwidth intranets will also facilitate the growth of PACS.

PACS Technology

PACS are computer network-based image storage, processing, distribution, and retrieval systems that can be used to capture, store, recall, display, manipulate, and print medical images and associated data. Digitally stored images can be accessed at any time from any PACS-enabled workstation, either within the radiology network or remotely (e.g., off-site). Ideally, PACS would facilitate an X-ray filmless environment, and most institutions using PACS see a considerable decrease in film usage (filmless, not film-free). Most PACS are interfaced to hospital information systems or radiology information systems and, to a lesser extent, clinical information systems. However, the ideal, paper-free, fully electronic patient record with demographics, images, clinical data, and other medical records fully integrated is very rare.

PACS are typically made up of the following components: Modality interfaces, a high-bandwidth network, two or more tiers of image-review workstations, two or more tiers of image archives, specialized servers, and interfaces to other information systems and peripherals (e.g., film printers and paper printers). These components are composed of

commercial off-the-shelf (COTS) hardware, COTS operating system software and specialized, developer/vendor-specific PACS application software. Each of these PACS components is discussed in detail below.

Modality Interfaces

All radiological imaging devices can be interfaced to a PACS. Digital modalities (e.g., CT, MRI) are usually interfaced directly with DICOM (see DICOM sidebar below) capabilities built in to the modality, as are newer digital modalities (e.g., digital radiography (DR)). Special add-on interface devices can be added to older models of imaging equipment to provide DICOM compatibility.

A traditional X-ray makes up 60% to 80% of all diagnostic radiography examinations. X-ray machines can be interfaced to PACS by using computed radiography (CR). With CR, conventional X-ray acquisition can be performed using a phosphor screen with energy storage capability as the X-ray image receptor. The phosphor screen is contained in a standard-sized radiographic cassette and can be used in existing radiographic tables and wall stands. After exposure, the cassettes are transferred to a reader system. There, the image plate is scanned with a laser device that stimulates luminescence proportionally to the local X-ray exposure. The luminescence signal is converted to an electrical signal and is digitized. The raw digital data representing the image are further processed to optimize the diagnostic content of the visual data. The processed image then can be stored, transmitted to a PACS, and/or printed via laser-printed film.

X-ray rooms with integrated CR devices or solid-state, flat-panel detectors are also available. For small volumes, X-ray film can be individually scanned with a film digitizer to convert them to digital format.

Networks

A PACS is typically configured as its own local area network (LAN) or as a dedicated sub-net in a wide-area-network (WAN) environment. Modalities (or modality interfaces), servers, workstations, and peripherals are interconnected with high-speed computer networks via coaxial, twisted pair, and/or fiber optic cables. Individual networks differ in design, but all have to take into account the very large amount of image data and the speed requirements of PACS. A variety of methods can be used within PACS networks, depending on the institution's legacy network and the geography of the institution. PACS networks have successfully used Ethernet (including 100 megabit and gigabit Ethernet), ISDN, T1 and T3 connections for remote sites, ATM, frame relay, and other high-speed data circuit routing and switching. It is important that the data circuit bandwidth be sized sufficiently large for the amount and speed requirements of the data. Internally, within the PACS, faster data throughput can be obtained using fiber-channel and other new storage and networking technologies (e.g., optical SCSI Storage Area Networks (SAN)).

A centralized PACS has a central archive around which all modalities and workstations are attached. This architecture allows equal access to the entire PACS. However, on a very large system, access can be slowed by one or more slow components (e.g., deep archive search). Although this architecture may include pre-fetching from the deep archive to the short-term archive, it does not require that the pre-fetch go to a specific workstation or distributed server.

Distributed PACS architectures have certain modalities connected to specifically identify distributed servers and/or archives. Attempts are made to optimize the server, workstations, and/or archive used for a particular modality or location. This can result in faster response times when the identified workstation is used, but it reduces flexibility and/or significantly reduces response time when a study must be read from a workstation cluster that is not the primary identified workstation for that modality or location. Both centralized and distributed topologies have been successfully implemented for PACS. However, to overcome some of the limitations of the centralized and distributed topologies, hybrid, "on-demand" systems have been developed. Figure 102-1 shows a sample topology for a large generic hybrid PACS. Images, upon completion of a study, automatically move from the modality to the near-term archive and the web-server. Demographic and image storage parameters, but not the images themselves, are stored on the database server. Any image can be viewed from any workstation. Images also can be automatically or manually routed to specific primary diagnostic workstations based on workflow parameters stored in the database server and/or individual requests (e.g., requests to push an image to a specific location or requests to pull an image from a specific location).

The server database acts as a traffic cop on the on-demand system. The database structure includes information about a particular image (e.g., date and time of acquisition, patient demographics, and modality), but not the image itself. When users select an image based upon a certain criteria, the database locates the image that meets the criteria, identifies and notifies the archive (short or long-term), and requests the archive to pull the image and route it to the workstation. Typically, an additional server is used to connect the database and archives to the web-based workstations. In addition to requiring more sophisticated server databases, the on-demand systems work best when there

is a high degree of interoperability between the RIS (Radiology Information System) and the PACS.

Workstations

Primary diagnostic workstations are used by the radiologist to view images for patient diagnosis. These workstations require the highest resolution and speed. Workflow must also be optimized as the radiologist might be reading a large number of studies in one day. Comparisons with prior studies might be required. These diagnostic workstations replace the motorized view boxes that are typically used in a film environment. Primary diagnostic workstations are required to display an image in sufficient resolution, comparable to film for film-based modalities, for the radiologist to make an accurate diagnosis. Images are selected based on a wordlist that comes from the modality or the RIS. Workstation users can review and manipulate (e.g., magnify, rotate, zoom on a region of interest) the images and add, edit, and delete annotations for later reference by themselves or other clinicians. High-resolution CRTs of up to 2048 × 2560 (2 K × 2.5 K) pixels are required. Multiple displays (2 or 4) are often used to view multiple images and/or do serial comparisons against prior studies or multimodality comparisons of the same current region of interest. Except for some specialized applications (e.g., nuclear medicine or ultrasound), displays are monochrome, gray-scale monitors.

Images also must be sequenced and displayed in a consistent manner, based on the needs and desires of the radiologist, modality, and type of study. Configuration sets are built so that the appropriate formats for display and sequencing are available based on the specific radiologist user's log-in, the modality, and the type of study (e.g., anatomy). These configuration sets are sometimes called "hanging protocols" based on their historical comparison to hanging multiple films on motorized X-ray view boxes in a certain order and place.

All primary diagnostic workstations offer some image manipulation tools including zoom, pan, magnify, invert, rotate, and measure (e.g., calipers). These workstations also allow image sequencing (sometimes called "stack mode") to dynamically view scan slices. In addition, specialized workstations are available that offer further manipulation

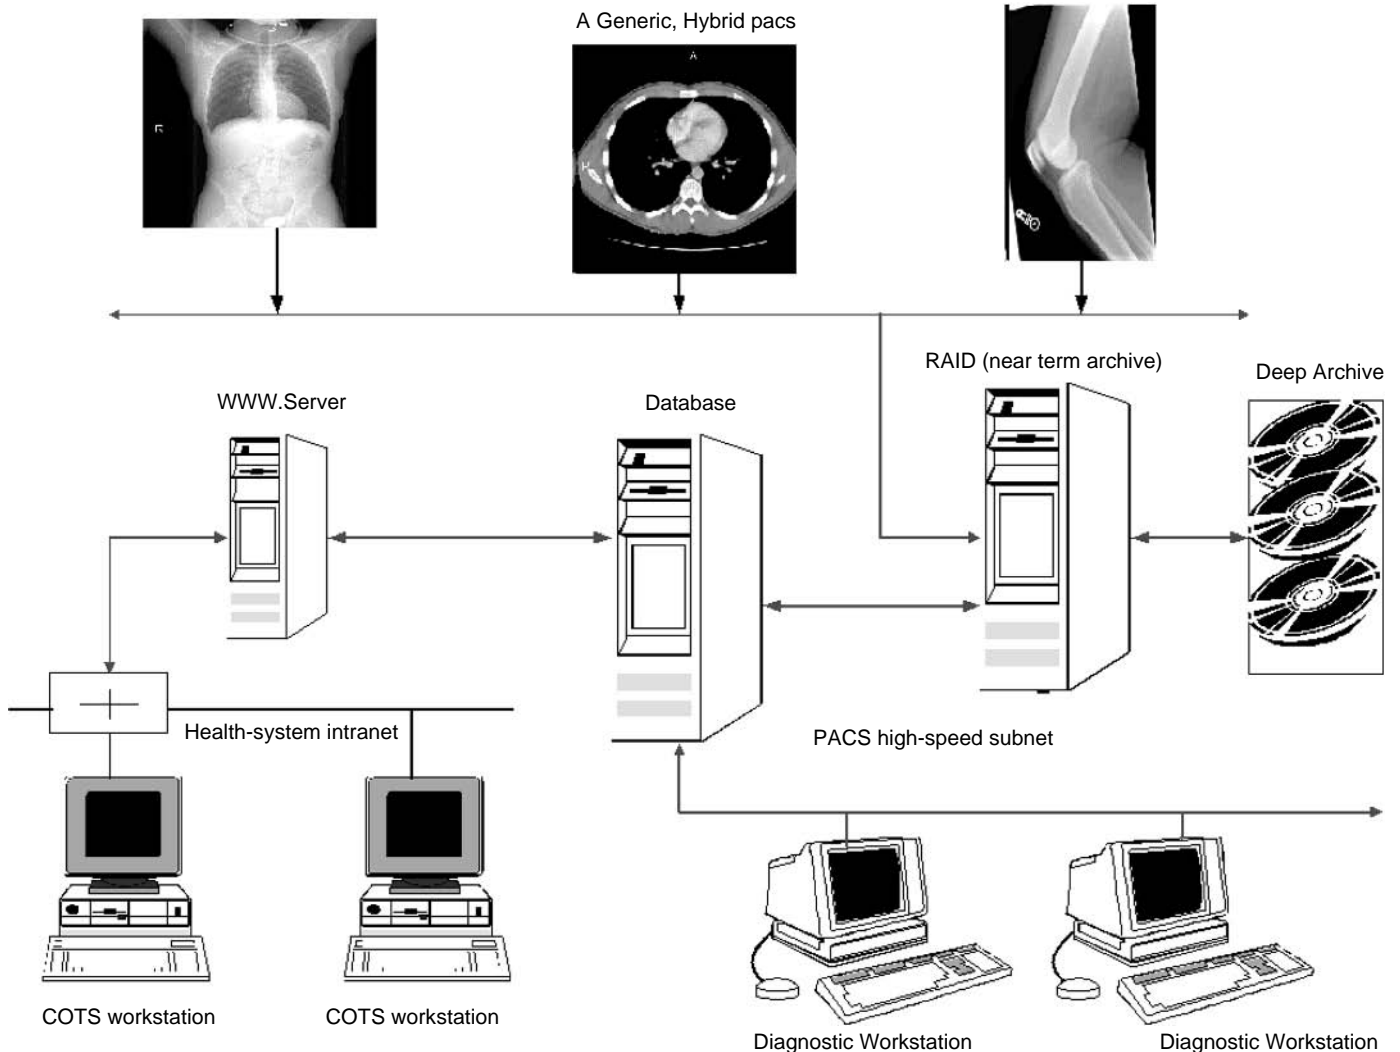

Figure 102-1 Sample topology for a large generic hybrid PACS.

similar to the workstations available with the modalities. Examples include CT-based virtual colonoscopy and 3-D rendering for surgery planning using CT or MRI.

These high-resolution monitors are expensive and require periodic calibration in order that each has consistent brightness and contrast so that a given study will look the same, regardless of which specific monitor is used to display the exam. These high-resolution monitors also decay in brightness over time, and various manual and automated calibration systems are in use to keep these monitors calibrated and to determine when their CRTs need to be replaced.

The primary task of the radiologist is to view the images and to report significant findings to the referring physician. In order to improve the radiologist's efficiency, various schemes for integrating report generation (e.g., speech recognition and typed reports) into the workstations have been developed.

Secondary review workstations, sometimes called "clinical review" workstations, are used by medical personnel (e.g., referring physicians) outside of the radiology department to review images in areas where image information is important and timely, such as intensive care units (ICUs), emergency rooms (ER), and orthopedics. Referring physicians might need to view an image and sometimes might show the image to the patient. This can be accomplished with a less sophisticated, lower-resolution display system. Specialized secondary review workstations are vendor-specific and expensive.

Tertiary-review workstations have even lower resolution and computer requirements. Most tertiary review workstations are web-enabled, commercial-off-the-shelf systems (COTS) with special PACS software and perhaps a special monochrome monitor and video interface/driver. The trend in secondary and tertiary review workstations is to use COTS and standard WWW networks in order to avoid the high cost of PACS workstations. (See cost section below). As the tertiary, COTS, and web-based workstations improve, custom secondary workstations will become obsolete because of their high cost.

Archives

Large radiology departments can generate more than 70 gigabytes of data per day. The ability to collect, store, retrieve, and distribute that large amount of data is one of PACS's primary challenges. Quick retrieval is always an important specification for the radiologist for initial diagnosis. Numerous studies have shown that images are looked at an average of x times within the first week, but only y times with the next z years ($x > y > z$). Therefore, a tiered approach has been used for image archive; near-term and long-term archives.

All images that are recent and/or otherwise likely to be retrieved in the near-future are typically stored on near- (or short-) term archive, usually using redundant array of independent disks (RAID) technology. RAID can store for a few weeks up to a year or two worth of images recently taken or images queued (i.e., pulled from the long-term archive) for likely retrieval, based on an upcoming appointment or other scheduled event. Unread studies are always stored in the near-term archive.

Long-term archival library systems are automated, robotic devices that index and load various types of media (e.g., tape or optical disks) into readers for retrieval of old studies. These devices can accommodate several different types of media and are expandable to hundreds of terabytes (one terabyte = 1000 gigabytes). As media design changes, and the cost per terabyte goes down, new jukeboxes and other long-term archival systems will be developed. Table 102-1 shows a comparison of long-term archive media. One concern in this rapidly changing technology is that the ability to read current media in several years may be dependent on keeping obsolete technology operational. An analogy would be trying to read eight-inch floppy disks today.

ASP Model

One of the newer solutions offered for the purpose of archiving is off-site storage via an application service provider (ASP). This remote archiving allows a hospital to outsource the hardware, software, and support for its image archive to a third-party. Images are retrieved via a web-browser application, and the ASP provider takes care of all the updates, uptime requirements, backup, and disaster recovery. Speed of retrieval is dependent on the same parameters as an in-house archive in addition to the speed of the wide-

area-network connection to the ASP. Some reports have shown speed improvements using an ASP because the ASP was able to use larger jukeboxes and, therefore, to keep all image data online compared to operator intervention for archive magneto optical disk (MOD) loading. A typical cost model for ASP archiving is to charge a fee per image and a fee per retrieval. Definitive, long-term cost studies have not yet been done—only projections to determine the point at which it becomes beneficial to use an ASP rather than in-house storage model, and vice versa, have been made.

Another similar idea to the ASP archive is to locate an institution-wide archive in the information technology (IT) department and to archive all information systems including PACS and laboratory information system (LIS), in a centralized location.

PACS Performance

The archive section above discussed the large amount of data that can potentially flow through a PACS system in a period of time. Two of the challenges when handling this large amount of data are retrieval speed and fault tolerance (redundancy). Both add significantly to the cost of any robust PACS.

Speed

Radiologists demand fast retrieval time. They are used in viewing film that is pre-hung on motorized X-ray view boxes and as long as the appropriate prior files were hung, they can view serial comparisons and other relevant past films quickly. PACS technologies that determine retrieval and display speed are the speed of the workstation processor(s), with gigabytes of memory and special fast video interface cards, and the speed of the network (pipes) and associated routers and hubs (100 megabyte Ethernet minimum; gigabyte Ethernet or fiber to the workstation optimum). Pre-fetching optimization (make sure that the retrieval records are available in the near-term archive) and speed of the short-term and long-term archives also impact overall system performance.

New technologies are being developed that address both the speed and cost issues with PACS. One of these technologies is called Dynamic Transfer Syntax (DTS). DTS allows sending image information in a format where the transmitted resolution starts low and increases as the requirements for more resolution are demanded. For example, on a tertiary workstation, an image would only be sent up to the maximum resolution of the workstation, instead of clogging the network and slowing the workstation with a full resolution image. (See DTS sidebar below.)

Redundancy

Modern high-availability, high-cost computer systems can be designed to reach 99.999% up time. If the resultant downtime occurred all at once, it would amount to approximately five minutes per year. Such systems use redundant networks, redundant file servers, hot-swappable disk drives (drives that can be changed with the power on), RAID, hot swappable power supplies, multiple processor computers, and other high-reliability components. As PACS becomes more highly utilized in filmless environments, it becomes a critical system that must be operational at virtually all times. Several of these redundancy options also can increase speed (e.g., storage area networks (SAN) with optical fiber channel connections) but they also can significantly increase costs. Systems need to be designed to meet the up time requirements of the institution while at the same time meeting cost requirements. Five minutes of down time per year is excellent, and one hour of down time (99.99% up time) might be acceptable, but 99.9% up time (~ 8 hours of down time) might not be acceptable, particularly if it occurs all at once. Standard COTS computers running Microsoft NT 4.0 are designed for 99.5% up time (i.e., two days of down time per year).

One promising new computer technology combines redundancy requirements with load balancing to offer speed and advanced fail-safe features. Instead of installing redundant servers that are in a standby (e.g., mirror) mode, these systems use software to manage clusters of servers that look like one host to the end-user but balance the workload between computers. This improves performance while all servers are working properly; senses problems; and then allows continued operation, albeit at lower speed, if one of the servers fails.

Table 102-1 Archive Media Comparison (Anon (b), 2001)

Archive media	Media cost/megabyte	Speed	Advantages	Disadvantages
RAID	High	Fastest	Used for all near-term archives.	High price per gigabyte. Not removable media
DLT and dual spool tape	Low to moderate	Slow to moderate for dual spool	Lowest cost media. Highest capacity media. Newer dual spool systems are improving access speed. Relatively high transfer rate.	Slow seek times
MOD	High	Moderate	Used by most PACS vendors today. Sturdy form factor for long-term, off-line storage. Seek times are good.	Transfer rates slow
DVD	Moderate	Moderate	Commercial/consumer use may drive prices considerably lower.	Commercial/industrial DVD standards are not mature.
On-site data center	varies, but potentially lower	varies, slower than local storage	Consolidates archive.	Needs high-speed network. Institution priorities may not be PACS priorities
ASP	varies, but potentially low cost when all costs are figured in	varies, slower than local storage	Institution does not need to worry about variable costs, system upgrades, backup, disaster recovery, staff support.	Loss of control. Potential speed issues.

Data Compression

With the large storage requirements of PACS and large bandwidth requirements for its networks, the PACS would seem to be a good candidate for compression. There are two primary forms of compression: Lossless and lossy. Lossless compression results in no image degradation and typically can average only a 3:1 compression ratio. Lossy compression results in some image degradation but can reach compression ratios of as high as 200:1.

There are two popular image compression methodologies: Joint Photographic Experts Group (JPEG) and wavelet. JPEG is most common and is included in the DICOM standard. Wavelet allows higher compression ratios and is being investigated by the DICOM committee for standardization and inclusion in a future update of the DICOM standard. ECRI (Anon, 2001) recommends that, for now, only lossless compression be used on any image that will be read by a radiologist, at least until the legal issues surrounding the use of lossy compression are resolved. In addition, ECRI recommends the use of JPEG compression until wavelet compression standards are approved.

Cost Considerations

PACS technology is expensive (see Table 102-2). Four-headed diagnostic workstations can cost upwards of \$150,000 per workstation. Infrastructure improvements are frequently required and can be expensive, depending on the size, age, and type of building construction and various regulatory issues that could get in the way of the improvements (e.g., asbestos abatement).

Savings from implementing PACS have been reported to range from \$4 per imaging study (savings in film and associated film processing and supply costs) to \$12 per study (e.g., film savings plus productivity improvements, file room staff reductions, and film storage space savings.). At 250,000 studies (films) per year, savings would be between one million and three million dollars. A PACS implementation for 250,000 studies per year with 20 diagnostic workstations will cost approximately \$5 million dollars in the year 2000. With annual support (software and hardware) estimated at 10% per year, annual upgrade expenses estimated at 10% per year, and a system lifetime of seven years for depreciation purposes, payback is between three years and never, based on the \$4- or \$12 per-study savings, respectively.

Improvements in technology and hospital infrastructure present opportunities to improve the cost-effectiveness of a PACS purchase and implementation. These include the following:

- Project timing (i.e., coordinating PACS implementation with the installation of high-speed network infrastructure in new buildings and during major remodels).
- Increasing and optimizing the use of (existing) web-based workstations as much as possible
- Using an institution-wide archive
- Reducing the transition time of the simultaneous use of both PACS and film-based technologies for the same modality
- Radiology department productivity improvements from workflow optimization (requires tight integration of PACS and RIS)

Ongoing Support

A PACS is dynamic, and ongoing technical support is extremely important. After implementation, a support team is required to keep the PACS operating effectively. The size of the system and the amount of in-house (vs. contracted) support will determine the size of staff required, and its required skill level. Of course, in the PACS cost analysis, expenses for support staff (contracted or in-house) need to be included. While PACS will allow a reduction in file room support staff, it will cause an increase in IT support staff. Although far less IT staff are required than file-room staff, IT staff have much higher salaries.

Table 102-2 Sample Hardware and Software Initial and Support Costs

Item	Hardware and software cost	Application
PACS software, MOD long-term archive, RAID short term, web-server	\$2,000,000 (rough estimate) depending on redundancy, size of RAID, size and media of long-term archive	Main system
(5) 4-headed high-resolution Diagnostic Workstations	150,000 each = \$750,000	Radiologists = primary read workstations
(15) 2-headed high-resolution diagnostic workstations	\$75,000 each = \$1,125,000	Radiologists = primary read workstations
Secondary access (use web-based COTS) with improved video	200 each × \$5000 for PC, video and software license \$1,000,000	Secondary read
Capital equipment and software subtotal	\$5,000,000	
Annual software and hardware support @ 10%	\$500,000 per year	
Annual upgrade expenses	\$500,000 per year	

PACSs are continually changing, with the typical vendor offering one or two major upgrades per year, and many more minor upgrades for bug fixes. Installing and implementing upgrades probably causes more down time than hardware failure or any other scheduled or unscheduled system work. Validation of upgrades prior to installation is one support concern, particularly in a multi vendor PACS environment (e.g., making sure that new PACS archive version a.0 works with new CR software b.2.).

The following is a short description of two typical support staff jobs:

PACS Director/manager: This person's job is to direct the overall PACS effort; to act as a liaison among the PACS vendor, PACS users, and hospital administration; supervise the data administrator; and coordinate all support (i.e., in-house and/or vendor purchased support).

Data administrator/system administrator: Any PACS will have routine data support requirements for building data tables, correcting data problems, performing routine backups, and training end-users. For most large systems, provisions must be made to provide some support 24 hours per day, seven days per week.

PACS Installation Planning

Prior to purchasing a system, it is critical to understand how a system will be used. Will the majority of the radiologists be performing primary reads in a modality-specific reading room, a central PACS reading room, or from their office? Will the PACS hardware (e.g., servers, backup jukebox.) be located in the radiology department, the IT department or somewhere else? How should the radiology department workflow change to optimize productivity with a PACS? Where will the CR readers be located? Considering that 70% of a typical radiology department's work is plain film and that the expense of DR is high, in order to digitize this plain film work, CR most likely will be utilized as an integral component of the digital radiology department. Where will the PACS administrator's office be located? Ideally, it should be near the PACS hardware. How and where will referring physicians review images (e.g., PACS secondary workstations, any web-based PC)? What are the PC requirements for PACS web-based image viewing?

Reading Room

PACS installations will have one or more reading areas set up for reading images, either by modality (e.g., MRI reading area, CT reading area, or CR reading area) or by anatomy (e.g., body reading area, neuro reading area, bone reading area). System requirements will determine networking cabling parameters (e.g., fiber or category-5 twisted-pair cable). It is good planning to include additional cable drops whenever cabling is first installed or upgraded. Most systems are flexible enough to allow reading from any primary diagnostic workstation, although some modalities might require specialized workstations. For example workstations for ultrasound and nuclear medicine studies utilize color displays, and some MRI and CT studies require 3-D and other more sophisticated tools.

Lighting is one of the most critical factors that must be addressed in PACS reading room design. A PACS reading room should have limited extraneous ambient light coming from behind the workstation. Background lighting and glare issues can have a significant effect on the readability of the images on the workstations. Indirect lighting is critical to the room design, including desk lamps for reading paper reports. These simple design criteria become very complex, if not impossible, when mixing film-based reading systems (e.g., motorized X-ray view boxes with their banks of high-intensity bulbs) with PACS workstations in the same room. Obviously, ample electrical outlets and HVAC are also required.

Challenges

All vendors of DICOM-compliant devices will provide a DICOM conformance statement for each device. DICOM conformance statement review continues to be a critical, albeit complex, task that must be performed for each pair of PACS components and modalities that must communicate with each other. This comparison must be performed before initial PACS implementation for existing and new equipment. DICOM compliance review also must take place prior to any upgrades or additions to the PACS or the modalities. Where in-house staff are not capable of performing DICOM conformance statement reviews, institutions should consider hiring outside experts to ensure that the compliance is complete and that the devices will function as planned. This is particularly critical when the pair of devices being investigated is provided by two different manufacturers. One common cause of problems in multivendor PACS is when incompatibilities occur because one of the systems is using private data that the other system does not understand.

Improved workflow can have a significant productivity impact on the radiology department. One technology issue that would significantly improve workflow is improved integration between RIS and PACS. Currently, unless the RIS and PACS are bought from the same vendor (and sometimes not even that helps), integration is minimal. Examples of improvements needed are reducing the need for redundant data entry (e.g., demographics, time of exam start, and exam complete), and automatic sending of messages from the modality to the PACS and/or RIS open exam completion.

In the operating room (OR), surgeons frequently need to refer to X-rays during surgery, and ORs have a high amount of background light. Many ORs are crowded with video and other equipment. Therefore, one PACS challenge is to develop easy-to-use systems (hardware and software) with high-luminescence flat panels or other viewing technologies that can coexist in the high ambient light environment.

Another challenge is the integration of the radiology PACS and its secondary workstations with some of the specialty areas and their need for specialized mini-PACS. These

specialized systems are typically purchased separately, and portions of them are redundant in function to the radiology PACS and its archive. Examples of this include modalities where color is essential (e.g., color Doppler studies in ultrasound or nuclear medicine), motion studies (e.g., cine loops for cardiac catheterization labs or echocardiography), physiological data integration with images for cardiac catheterization labs, and treatment planning in radiation oncology.

Summary

PACS technology will continue to be driven by improvements in computer power and lowering of prices for COTS. The specialized applications for servers and archives will use the newest and more expensive computer technology, while the bulk of the workstations will use COTS. The further implementation of higher-speed intranets will allow the secondary viewing of images from any workstation. New standards (e.g., DICOM-2000/JPEG-2000) will improve the speed and interoperability of systems, while new digital modalities (e.g., digital mammography) will also increase the scope of PACS. Such systems will allow the radiologist to perform a primary read from any geographic location, thereby increasing the use of, and lowering the cost of, teleradiology.

Dynamic Transfer Syntax

A University of Pittsburgh team has developed dynamic transfer syntax (DTS), a new protocol for lower-cost and enterprise-wide image distribution. The DTS technique could reduce the need for expensive high-bandwidth networks and high resolution, high-powered primary workstations. DTS was developed to meet the demands of referring physicians who require resolution and image-manipulation features that are similar to those that radiologists have in their own clinics, offices, or operating rooms. Research at the University of Pittsburgh showed that in 60% of the cases, a timely, written radiologist's report (with no images) was sufficient for the referring physician. In another 20% of the cases, a lower resolution set of images was also required. In the final 20% of the cases, clinicians wanted to review at least some of the images at the same resolution, and with similar image-manipulation tools as the radiologist had. Furthermore, the referring physicians wanted access to any and all archived exams for the patient so they could determine which exams are relevant for additional review. Without these capabilities, the referring physicians would still require film and would obviate a major reason for using PACS (i.e., reduction or elimination of the use of X-ray film).

Typical diagnostic-quality PACS workstations can cost upwards of \$150,000 each. To solve the above problems without investing hundreds of thousands of dollars, DTS was developed. DTS uses wavelet-based compression to send the requesting workstation data that fits the requirements of the user, the network, and the workstation. The wavelet data scheme allows additional image detail to be sent only when the user needs it. When an image request is made, DTS determines the number of images and the resolution at which to transmit, after assessing the resources available at the workstation. This real-time image delivery scheme enables the use of less powerful networks, such as standard Ethernet (10 megabits per second or 100 megabits per second). In theory, DTS therefore allows full functionality on COTS workstations with standard network infrastructure. DTS is in its infancy and has not been widely implemented yet. It remains to be seen whether it will be as accepted in actual practice as it has been at its developers' sites and whether it can scale up to the demands of the large institutions with hundreds of referring physicians and therefore hundreds of workstations and hundreds of thousands of images. DICOM Sidebar

DICOM was developed as a digital-image transmission standard in order to enable users to retrieve medical images and associated information from digital imaging equipment in a standard format that would be the same across multiple manufacturers' systems. DICOM was designed to be very flexible. This explanation is based on DICOM version 3.

Standards-based electronic communication is commonly modeled as a set of layers, with each layer performing a defined set of functions such as the Open Systems Interconnection (OSI) 7-layer model promulgated by the International Standards Organization (ISO). This model (see Table 102-3) looks like a stack with the first (i.e., lowest) layer being the physical media (e.g., wire or fiber-optic cable) over which the information will be sent or received, and the top (i.e., seventh) layer being the application software. The middle layers concern character sets that are used to represent information, the rules for making connections over the physical layer, packet breakup and reassembly, communication between layers, and error handling. Each layer in the stack performs a well-defined set of functions and accepts input and provides output to adjacent layers only. Established rules allow communication between different devices at their corresponding layer.

One advantage of layered systems is that a layer can be replaced by a newer layer without affecting other layers. For example, if a new physical medium is 100 times faster than an older medium (e.g., fiber cable vs. standard Ethernet), only the physical layer must be replaced in order to take advantage of this additional speed.

Table 102-3 ISO 7 Layer Model

7	Application layer	Gives user applications access to network services
6	Presentation layer	Encodes and converts user information to binary data
5	Session layer	Opens, manages, and closes communication between computers
4	Transport layer	Sequences data packets and requests retransmission of missing packets
3	Network layer	Routes data packets across network segments
2	Data link (MAC) layer	Transmits frames of data from computer to computer
1	Physical	Defines cabling and connections

DICOM uses services to request communication with another device. The network protocol will indicate that the network is either available or busy. If available, DICOM initiates a series of actions that request an association with the other device. DICOM refers to the devices as "application entities" (AEs) because it is the application-layer software (i.e., the top layer in the stack) that initiates the communication process. The association establishment negotiates the capability of the application entity with which it is attempting to communicate by requesting a list of tasks that it needs to complete. The receiving-application entity then replies with the items on that tasks list that it can do. Subsequent exchanges are based on the capabilities that the two application entities have in common. For example, if the two application entities need to exchange numeric information that is more than one byte long, then they first need to determine how their numeric data is byte-encoded. Is the most significant byte stored and sent first (i.e., "little endian"), or vice versa (i.e., "big endian")? If two devices use the opposite representations to exchange numeric data, such an exchange will be erroneous unless the devices know that the representation is incorrect and they can facilitate conversion. DICOM allows for both methods of representation and resolves the one that is to be used at the association phase of the communication.

DICOM breaks the data that it needs to send, into a series of elements. Applications might have different ways of representing the values contained in any given data element. DICOM has very specific definitions of the different data types allowed, called "value representations" (VR). Examples include text strings of different maximum lengths, binary numeric data, and dates and times. DICOM historically defines the VR in a data dictionary. In DICOM 3 and higher VRs are explicitly imbedded in each data element. DICOM allows both methods, and this is one of the issues negotiated between application entities at association time. The VR and the byte order are part of a set of information required for a successful interchange. This set is called the "transfer syntax." As noted elsewhere in this chapter, some of the newer technologies (and proposed DICOM standards) support *dynamic* transfer syntax, which allows the defined association to change parameters "on-the-fly," dependent on the circumstances of the data requested (e.g., requestor needs low resolution to look at thumbnails, but higher resolution after a particular image is selected for full-screen viewing).

DICOM has also adapted some conventions from other standards, such as the patient name format specified by the HL-7 standard (Health Level 7). DICOM 3.0 also defines the relationship between entities; for example, the way a patient identifier (e.g., name, medical record number) associates itself with a study; the way a study associates itself with a series of images; and the way a series of images is associated with a radiologist's report. This object-oriented model is called an "entity-relationship model." Each of the entities in an entity-relationship model has certain attributes. For example, the patient entity has the attributes of details such as last name, first name, medical record number, height, weight, and date of birth. The DICOM standard defines several information objects (e.g., patient, study and modality) and their mandatory, optional, and conditional attributes. Conditional attributes are required (mandatory) only under certain circumstances. Whenever DICOM needs to uniquely identify an object (e.g., patient), it uses an international standard technique for generating a unique identifier, called a "UID."

DICOM provides standardized services that are used with the information objects. DICOM builds its more common services out of a set of service elements called "DICOM message service elements" (DIMSEs). There are 11 DIMSEs that fall into the categories of operations (e.g., store or query-retrieve) or notifications (e.g., error report or event report). Some DICOM services require more than one DIMSE. For example, query-retrieve is made up of the "find," "get," and "move" DIMSEs. These simple DIMSEs are used to build most of the services in a PACS. Because of the object-oriented nature of PACS, services are referred to as "service classes." It is also important to know whether a device provides a service, or uses a service, or both. As part of the negotiation process discussed earlier, it is communicated whether a device is a service-class provider (SCP), service-class user (SCU), or both. The service classes and information objects are combined to form the functional units of DICOM. This combination is called a "service-object pair (SOP) class."

A DICOM conformance statement follows a standard structure, making comparison between two manufacturers' DICOM conformance documents possible. The contents of the conformance statement include the implementation model of the application, the presentation contexts to be used, the manner in which associations are to be handled, the SOP classes to be supported, the communication profiles to be used, and any extension, privatization, or specialization.

The implementation model of the application is a diagram that shows how the application is associated with local (within the medical device) and remote (across the DICOM interface) activities. Presentation contexts consist of the SOP class(es) and the transfer syntaxes used for that SOP class. The conformance statement must describe the way an activity handles associations and whether or not it will handle multiple associations, and, if so, how many.

The list of SOP classes supported is one of the key portions of the conformance statement. This list describes the service classes and information objects that will be offered and accepted. The communication profile indicates whether any or all of the available communication profiles are used. The available communication standards are point-to-point, OSI, and TCP-IP.

The final section of the conformance statement lists privatization, specializations, or extensions to the standard classes. Extensions are supersets of standard classes and should not cause major compatibility problems. Neither specialized nor private SOP classes use DICOM-defined UIDs and, therefore, they are prone to causing manufacturer-to-manufacturer incompatibilities. This is a common cause of problems in multivendor PACS where unknown incompatibilities are caused by the use of private data.

Consider the following example: Suppose that a technologist is sending ("pushing") an MRI study from an MRI scanner to a workstation using DICOM so that the radiologist can perform a preliminary read prior to the patient leaving the scanner area. The operator selects the specific study to send to a specific workstation. The communication protocol used (typically TCP-IP) will carry the study from the scanner to the workstation. The application software at the MRI scanner console begins assembling a series of SOP instances (i.e., MRI storage instances). The DICOM process begins the communication process by having the MRI scanner application request an association with

the workstation. The communication network has previously handled the steps of setting up a communication channel between the MRI scanner and the workstation. During the association, the MRI scanner will provide its presentation context, telling the workstation that it supports the MRI image storage SOP class as a service class user. The MRI also declares that its transfer syntax is implicit VR "little endian." The workstation replies that it supports the MRI SOP class as a service class provider and user. The workstation replies that it can use VR "little endian" transfer syntax. Notification of acceptance of the association is sent to the respective devices.

The MRI sends the request for storage service, along with the images to the software that assembles the DICOM message by putting together the necessary command and data elements. The DIMSEs needed for the storage-service class and the data set are handled by the communication stack, where the message may be broken up into smaller packets. The message is reassembled into the DICOM message in the communications stack (ISO middle layers) of the workstation. The reassembled DICOM message, including image data, is received by the application in the workstation that stores the MRI images in a local cache for display and, if necessary, manipulation.

The speed of this process is dependent on the amount of data, the speeds of the storage media, the workstations, and the network infrastructure. Typically, once the association is established, it can be reused for multiple SOP instances. Associations must be closed when they are no longer needed or when computer resources are being wasted and slowing the system down.

Acknowledgment

Thanks to J. Anthony (Tony) Seibert, Ph.D., medical physicist at the University of California Davis Medical Center, for his review of this chapter.

103 Wireless Medical Telemetry: Addressing the Interference Issue and the New Wireless Medical Telemetry Service (WMTS)

Donald Witters

Physicist, FDA, Center for Devices and Radiological Health
Rockville, MD

Caroline A. Campbell

ARAMARK/Clarian Health Partners
Indianapolis, IN

The use of wireless medical telemetry in hospitals is expanding as one way to help meet the ever-rising cost of health care. As users of medical devices know from experience, the radio signals transmitted from the patient to the monitoring station are vulnerable to electromagnetic interference (EMI), which can present a real risk to patients being monitored. If these signals are interfered with or lost while the patient is suffering a significant adverse health event (cardiac arrhythmia, for example), the medical response could be delayed, and serious patient consequences are likely to result. Because of the importance of these signals and the likelihood of EMI with these vital transmissions, the Food and Drug Administration, the Federal Communications Commission (FCC), medical device manufacturers, and the health care community banded together to examine the EMI issue with wireless medical telemetry and developed solutions to minimize the risks to patients posed by EMI. These efforts culminated in the creation of the new Wireless Medical Telemetry Service (WMTS), with its separate frequency spectrum and coordination, which is designed to reduce the risk of EMI to the vital patient telemetry signals from other radiofrequency transmitters operating in the same frequency bands.

The purpose of this chapter is to provide a brief summary of the EMI problems for the traditional wireless medical telemetry widely used in hospitals and clinics and provide information that clinical engineers can use to assess their situation and implement solutions to reduce the risks of EMI. This chapter will briefly touch on the concerns about EMI with

medical devices and what has been done to address these concerns. It will highlight the creation of the new WMTS and will relate the need to make immediate assessments of medical telemetry equipment and plans to address the coming changes to the airways where wireless medical telemetry has been used. The last section in this chapter speaks to ways of assessing the EMI risks. Each hospital and situation will likely be different, requiring familiarity with the local situation (e.g., numbers of telemetry channels being used or planned) and the risks and other factors that commonly arise with major technology changes.

The rapid changes to the radio spectrum where medical telemetry has traditionally operated make it imperative that hospitals and clinics change their approach for medical telemetry systems in order to minimize vulnerabilities and risks of EMI. Further, the issue of EMI with wireless telemetry must be looked upon as a part of the whole picture of EMI with medical devices. Simply changing the wireless telemetry will not eliminate the threat posed by EMI to other sensitive medical devices. At a time when medical and communications technology are rapidly changing, the clinical user is faced with choices about the deployment of wireless technology and other radio transmitters in their facility that must be balanced with considerations for the numerous other medical devices in the facility that are susceptible to EMI. Only through a basic understanding of the complexities of medical device EMI and the drive toward electromagnetic compatibility (EMC) can the clinical engineer begin to appreciate the risks involved and ways to undertake procedures

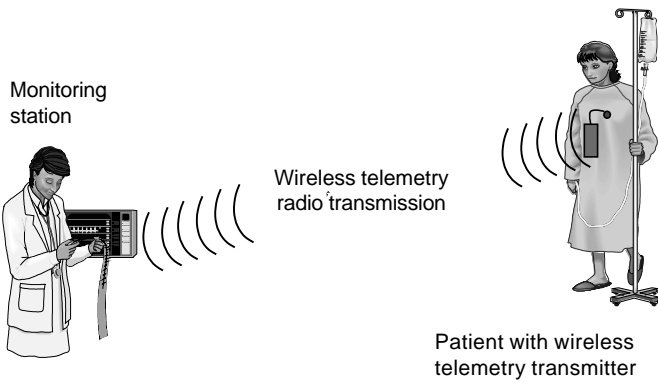

Figure 103-1 Typical wireless telemetry components.

that will minimize these risks (Witters, 1997; Witters and Silberberg, 1997). In the end, all health care facilities must come to grips with the promise of wireless technology and the increasing risk of EMI on patient safety.

Wireless medical telemetry as it is widely used today is a relatively simple way to maintain physiologic monitoring of patients while allowing them to move freely without wires connecting the patient to a stationary monitor, helping to speed their recovery and thus lower costs. Figure 103-1 illustrates a basic configuration for wireless telemetry, consisting of a small, patient attached, limited range radio transmitter sending physiological data in real time to a central monitoring station. Each of the components (patient attached physiological sensor and radio transmitter, radio signal, and central monitoring equipment) is susceptible to EMI. However, because of the changes to the radio airways and allocations used for radio transmission, and the greater use of “wireless” radio transmission links in and around the hospital, the present installed base of wireless telemetry is a greater risk by EMI than ever.

Concerns for EMI and the Drive toward EMC

To understand the drive toward electromagnetic compatibility (EMC), which is essentially the opposite of EMI, the reader must have a basic understanding of these terms and the ways in which they relate to medical devices. EMI is the disruption of the medical device function by electromagnetic energy (EM), which can take the form of any of the following:

- Radio frequency (RF) radiation (e.g., transmissions from radio, TV, radar, and cellular telephones)
- Conducted electrical energy (e.g., electrical surges, sags, and harmonics, and higher-frequency signals that can be induced onto leads and conducted into the device)
- Electrostatic discharge (e.g., lightning and the discharge of static electricity that humans can carry on their bodies to a lower-voltage potential on a medical device)

Each form of EM energy can disrupt medical devices on its own or in combination with one or more of the other forms. In the case of RF radiation, the threat from multiple transmitters can lead to even more complex situations that might be additive or subtractive. In

addition to the intentional transmissions from various transmitters, electrical currents flowing through a conductor induce electric and magnetic fields. Thus, all electrically powered medical devices, as well all electrically powered products and systems, create emissions that add to the congestion of EM energy in the environment.

The major two areas of concern for medical device EMC are: (1) device emissions and the effects of these on other devices and (2) the immunity from (or, conversely, the susceptibility to) the EM energy that is expected in the environment where medical devices are used. The key to EMC is to minimize the emissions and to maximize the immunity. In most cases, these two areas interplay. By minimizing the emissions with proper design and shielding, the susceptibility is also changed, and immunity to EMI is improved. The key point to remember is that both emissions and immunity are important parts of the drive toward medical device EMC. The AAMI TIR 18-1997 “Guidance on Electromagnetic compatibility of Medical Devices for Clinical/Biomedical Engineers-Part 1: Radiated Radio Frequency electromagnetic Energy” contains an excellent overview of medical device EMI concerns and ways to address these concerns for the biomedical/clinical engineer (AAMI, 1997). The JCAHO Environment of Care Series: EC/PTSM Series No. 2 contains several articles in this area. Also, see Geddes (1998) for examples of medical device EMI and Kimmel and Gerke (1995) for a good overview of medical device EMI/EMC and how to design, build, and test equipment for immunity to most common EM energy.

Traditional Secondary Status of Wireless Medical Telemetry

Wireless medical telemetry has worked fairly well for many years as the secondary users of the RF spectrum between the high power channels for the Private Land Mobile Radio Service (PLMRS) and on vacant local television channels. According to the FCC rules, as the secondary users of the spectrum, medical telemetry users must accept interference but not cause EMI to the licensed primary spectrum users (e.g., the TV broadcasters). In general, the low radio output power of medical telemetry poses little threat to the high-power broadcasters, and for many years there were adequate numbers of low-power PLMRS channels and unused TV channels (because the older analog TV broadcasts required vacant spectrum between channels). Thus, in a real sense the TV broadcasters of soap operas about hospitals had more rights to use the airways than the hospital transmitting vital signals from actual patients.

However, with the coming of the digital age in the early 1980s, and the ever-changing and increasing needs for radio spectrum, the available channels and frequencies where medical telemetry is able to function have dramatically decreased. In the same space of time, medical technology has increasingly utilized communications improvements to speed the delivery of medicine. Thus, the two worlds of medicine and communications were placed on a collision course, with medical telemetry restricted by its secondary status for the use of the radio airways and the communications industry rushing to meet ever-increasing demand.

Problems for EMI with wireless medical telemetry and concerns about the changing radio spectrum have long been known (Pettijohn and Larsen, 2001; FCC, 1999). In 1994, a group of wireless medical telemetry device manufacturers petitioned the FCC to allow medical telemetry to use more frequencies. With FDA support, the FCC granted medical telemetry the ability for secondary use of vacant TV channels 14 to 69 (470 MHz- 806 MHz) in 1997. This expanded the frequencies for use by medical telemetry that had been limited to vacant TV channels 7 to 13 (174 MHz to 216 MHz). However, it was not until the initial test broadcasts of the new digital television (DTV) in early 1998 that the potential magnitude of the EMI problem with wireless medical telemetry came to be fully recognized.

A survey done by the American Society of Healthcare Engineering (McClain, 2002) of several hundred hospitals showed that nearly 40% of the wireless medical telemetry used in the U.S. utilized vacant TV channels to carry the radio signals from patient to monitor. Approximately 60% were found to use the PLMRS in the 450 MHz–470 MHz frequency range. A few hospitals were using equipment operating in other frequencies, such as the Industrial, Scientific, Medical (ISM) bands centered around 915 MHz–2450 MHz. Table 103-1 summarizes the various frequencies where wireless medical telemetry can operate.

Table 103-1 Wireless Medical Telemetry Operating Frequencies

Frequency band	Use status	Power output	Limitations	Recent changes
TV channels: 174–216 MHz (Ch. 7–13)	Secondary	1500 µV/m @ 3m transmissions confined to a 200 KHz band	Vacant channels	No new FCC approvals after October 2002
Low Power Radio Service (LPRS): 216–217 MHz	Secondary	100 mW	Nearby transmitters must coordinate with Aricebo Observatory in Puerto Rico	
TV Channels: 174–216 MHz, 470–669 MHz (Ch. 14–46)	Secondary	200 mV/m @ 3m,	Used on health care premises, vacant channels, coordination required for channel 37	No new FCC approvals after October 2002
PLMRS: 450–470 MHz,	Secondary	20 mW without separate license, low power use <2W may need license	Limited use of offset channels, license required for high-power use	No new FCC medical telemetry approvals after Oct. 2002. Freeze on high-power use and channel width changes in 450–460 MHz lifted as of Jan. 2001; freeze on 460–470 MHz lifted October 2003
WMTS: 608–614 MHz	Primary	200 mV/m @ 3m, operation within <1.5 MHz bandwidth	Register with frequency coordinator required, coordination required near radio astronomy	
WMTS: 1395–1400 MHz, 1429–1432 MHz	Primary	740 mV/m @ 3m, operation within <1.5 MHz bandwidth	WMTS is primary on part of this band in certain locations, Itron (utilities) is 150 µ 1/m at the location in primary on part of band in the WMTS registered health care other location facilities	Government operations cease Jan. 2009 for 1395–1400 MHz; Jan. 2004 for 1429-1432 MHz
WMTS: 1427-1432 MHz 902–928 MHz, 2400–2500 MHz, 5725–5850 MHz	Primary/ Secondary			

Most of the radio spectrum bands used for wireless medical telemetry have restrictions and limitations on these transmissions, and some are being changed in ways that will dramatically increase the vulnerability of present device systems to EMI from other in-band transmitters.

DTV Incidents

The collision between the licensed broadcasters and medical telemetry became clear in March 1998, when the wireless medical telemetry in two Dallas hospitals was disrupted by the initial DTV test broadcasts from a local TV station (FDA, 1998). Quick work by the clinical engineering and nursing staff at these hospitals avoided the situation of unmonitored patients. Fortunately, no patients suffered cardiac arrest or other serious condition while their wireless telemetry was interfered with. The clinical engineers at one institution, Baylor Medical Center, went further and were able to identify the source of the problem as a TV signal covering nearly the entire channel where their telemetry was transmitting. They tracked the TV signal and contacted the local broadcaster to ask that the signal be stopped (FDA, 1998). It seems clear from Figure 103-2, which depicts a typical TV channel over its normal 6-MHz channel width and an idealized DTV signal, that the DTV signals take the entire channel spectrum, leaving no space for low-power radio signals in these frequencies. The result is that the wireless medical telemetry is overwhelmed by the DTV signal on the same channel. As the medical telemetry has no protections from the “in-band” transmissions of the DTV, it simply will cease to get the patient information through to the monitoring equipment and nurses.

However, these incidents brought the situation into focus for the FCC and TV broadcasters, who clearly understood the needs of real patients. With the U.S. acceptance of DTV, the FCC mandated that all TV broadcasters would be allocated an additional TV channel for DTV, with the anticipation of phasing out the older analog technology by the year 2009. This meant that medical telemetry users were left with far fewer vacant TV channels as they had had previously, and the potential for EMI from the DTV signals. Information on the allocations for DTV can be found on the FCC website: www.fcc.gov/healthnet/dtv. The FDA issued a Safety Alert aimed at the hospital and clinical users of medical telemetry, advising them to coordinate with local TV broadcasters (FDA, 1998). It also initiated a meeting with all of these parties to develop ways that would address the immediate issues with wireless medical telemetry, with a goal to develop long-lasting solutions including protected, separate frequencies and coordination. Because of the concern for medical telemetry use in hospitals, the American Hospital Association (AHA) took the lead in organizing a Wireless Telemetry Task Group with the goal of developing specific recommendations for solutions.

Concerns with PLMRS Telemetry

From information in the 1998 ASHE survey of wireless medical telemetry nearly two-thirds of the wireless medical telemetry operates in the frequency range between 450–470 MHz as secondary, low-powered transmitters (see Figure 103-3). Most users are actually operating in this band between 460 and 470 MHz. In the late 1980s, the FCC determined that this band was crowded and should be “refarmed” or changed to allow for increased numbers of channels and users. The plan, adopted in 1995, changed this band from its present 25 KHz bandwidth channels to 12.5 KHz channels with the eventual goal of 6.25 KHz channels. The PLMRS refarming plan also eliminated the low-powered interchannel frequencies that most wireless telemetry used, instead making all users compete for the higher power 6 KHz channels. The narrower channels, combined with newer digital transmissions, will allow several more users access to the PLMRS band. However, it was clear that under this plan all medical telemetry operating in the PLMRS band were immediately vulnerable to EMI from any number of mobile radio transmitters that would use the new allocations. Figure 103-3 and 103-4 illustrate shows the cascade of refarming the PLMRS band from the 25 kHz channels, through the 12.5 KHz channels, into the 6.25 KHz channels. Because of the potential conflicts, a group of the medical device manufacturers petitioned FCC to delay the refarm plan on this band. Fortunately, the FCC recognized the possible conflicts for

Illustration of Older PLMRS Channels
25 kHz Primary channels and Telemetry “Offset” channels

Figure 103-3 Illustration of PLMRS 450–470 kHz radio signals with wireless medical telemetry in offset channels.

medical telemetry and placed a freeze on implementation of the refarming. Because of the success in creating the WMTS (see below), the FCC has (announced January 29, 2001) lifted the freeze on high-power applications for the new 12.5 KHz channels in the frequency range 450–460 MHz (FCC, 2001).

Origins of the Wireless Medical Telemetry Service (WMTS)

The AHA Task Group looked at the issues for wireless medical telemetry and developed recommendations to address major areas of concern, including:

- A definition of wireless medical telemetry
- The medical needs for wireless telemetry
- The engineering and RF needs for telemetry
- Ways to raise awareness and educate users

The results of their work developed a clear definition of what wireless medical telemetry is and ways in which it has been used. This definition was used by FCC in creating the WMTS.

“Wireless medical telemetry is therefore defined as the measurement and recording of physiological parameters and other patient-related information via radiated bi or unidirectional electromagnetic signals. This technology may be contained within a health care facility or extend beyond to other buildings or locations.” (FCC, 2000)

The Task Group surveyed several hospital users and found that by using the present technology (transmitting at 0.8 bits per second per Hertz) up to 500 concurrently operated telemetry transmitters within a geographical area would require a minimum of just over 6 MHz of spectrum frequencies. The survey results indicated that the greatest uses for wireless monitoring are for adult electrocardiogram, 12-lead parametric monitoring, pulse oximetry, invasive blood pressures, and respiration (AHA, 1999 and FCC, 2000). Future needs were estimated to make use of at least double this number of concurrent transmitters within the same area and consequently require at least 12 MHz of spectrum.

Refarming of PLMRS 450 MHz to 460 MHz

Old channels vs New channels

Figure 103-4 New, refarmed 6.25 MHz PLMRS signals with old 25 KHz wireless medical telemetry signals.

Figure 103-2 Typical 6 MHz TV broadcast channel, with DTV signal overlaid.

The Task Group also identified spectrum candidates, with input by the FCC members, and rated the candidates for several factors, including: Needs for power consumption and transmitter power, vulnerability to EMI, multipath fading, effects of frequencies on humans, bandwidth available, costs for equipment and maintenance, and radiation efficiency. The frequencies chosen as the best candidates totaled 14 MHz and were located in 3 separate frequency bands: 608 MHz to 614 MHz (TV channel 37), 1385 MHz to 1390 MHz, and 1432 MHz to 1435 MHz. This forward-looking assessment allowed for bi-directional communications on separate frequencies, thus potentially opening the future for monitoring patients and treating them via patient-attached medical devices. In addition, the Task Group recognized the continuing need to coordinate use of the frequencies to avoid conflict within and without a hospital. In some urban areas around the U.S., there are several health care facilities using medical telemetry that are located within a short distance of each other. This is especially problematic in the northeastern U.S., where more than 1000 patients may be monitored within a mile of each other. The FCC has commonly used a Frequency Coordinator to oversee the use of various radio-transmission-frequency spectra. Thus, the recommendations included a frequency coordinator for the wireless medical telemetry.

The Wireless Medical Telemetry Service (WMTS)

On June 8, 2000 the FCC adopted the Report and Order ET docket 99-255 creating the WMTS for wireless medical telemetry (FCC, 2000). Under the WMTS, for the first time, medical telemetry has primary status and all of the regulatory protections that go with this status. This means that other transmitters that interfere with WMTS equipment will be in violation of the FCC rules and could face regulatory penalties. In addition, the WMTS will be overseen by the WMTS frequency coordinator, who is responsible for maintaining a database of the use of these frequencies and for facilitating sharing of these frequencies among hospital users and the remaining government operations at protected government sites. Users of WMTS are licensed by rule so that individual licenses are not required; instead, the WMTS users are expected to share the frequencies and to utilize the coordination within their locales. Authorized users of WMTS include authorized health care personnel, health care facilities, and trained technicians under the control of the health care facility. The FCC has chosen to define health care provider facilities as essentially 24-hour-type care facilities, with specific exclusions for mobile or home use.

Unlike the traditional wireless telemetry use of channelized transmission, the AHA Task Group recommended and FCC agreed that there be limited technical specifications and no channelization for the WMTS. This opens the WMTS for many different types of modulation schemes to carry important patient data and allows for the use of bi-directional transmissions, (i.e., from the patient to the monitoring equipment and back to the patient attached device). The minimal technical restrictions enable growth of the medical telemetry technology by allowing, for instance, the advanced communications technologies used in cellular communications to be used for WMTS. By looking toward the future challenges, the lack of technical specifications opens the way toward increased utilization while challenging the designers and users of these systems to maintain strong system integrity.

Subsequent to the creation of the WMTS, there were FCC actions that affected the 1427–1432 MHz band spectrum where part of the WMTS is located (FCC, 2002). Over the years, public utility companies have been using a radio transmitter system by Itron in this band (as secondary frequency users) to remotely read utility meters. Following negotiations among AHA, Itron, and the FCC, it was decided that the WMTS and Itron and other non-medical telemetry could share the frequencies in the band. Under the final plan WMTS is primary in part of the band and secondary in the remainder of the band, with the primary allocation determined by geographic location.

"Generally, WMTS operations are accorded primary status over non-medical telemetry operations in the 1427–1429.5 MHz band, but are treated as secondary to non-medical telemetry operations in the 1429.5–1432 MHz band. However, there are seven geographic areas in which WMTS and non-medical telemetry operations have 'flipped' the bands in which each enjoys primary status. These seven areas, termed the 'carve-out' areas, are (1) Pittsburgh, PA; (2) the Washington, DC metropolitan area; (3) Richmond/Norfolk, VA; (4) Austin/Georgetown, TX; (5) Battle Creek, MI; (6) Detroit, MI; and (7) Spokane, WA. In these seven areas, in contrast to the rest of the country, WMTS has primary status in the 1429–1431.5 MHz band, but is secondary to non-medical telemetry operations in the 1427–1429 MHz band (FCC WMTS web site, 2003)."

The key features of the WMTS are listed below.

Use of WMTS:

By health care facilities and professionals, licensed by FCC rule

Frequencies bands and technical specifications:

608–614 MHz, 200 mV/m maximum field strength at 3 meters
1395–1400 MHz, 740 mV/m maximum field strength at 3 meters
1429–1432 MHz, 740 mV/m maximum field strength at 3 meters (for important limitations on the use of this band, see Limitations of use below).

- Uni- and bi-directional transmission allowed
- Voice and video not allowed (physiological waveforms are not considered video)
- Limitations on out-of-band emissions
 - 1395–1400 MHz and 1429–1432 MHz bands, no channelization specified
 - 608–614 MHz (TV channel 37) band has limitations of spread spectrum technologies and limitations on assignments of channels so that no facility can have exclusive frequency use. Operations in this TV channel band are not protected from adjacent band interference from channels above and below this TV channel.

Limitations of Use:

- Use of the 1395–1400 MHz and 1429–1432 band is restricted in some geographical locations because of continued government use and a band plan arrangement with other users of the 1427–1432 MHz band. The restrictions related to government will phase out in 2009 and 2004, depending upon the band.

- Use of the 608–614 MHz band is restricted within 80 Km of several sensitive radio astronomy observatories noted in the FCC report and order (FCC, 2000). Written concurrence and frequency coordination near these observatories is required.
- In the 1427–1432 MHz band, WMTS is generally primary at 1427–1429.5 MHz and secondary from 1429.5–1432 MHz, except in certain geographic locations where the primary and secondary frequencies are reversed. See the FCC web site <http://wireless.fcc.gov/services/personal/medtelemetry/>

Frequency Coordinator:

- Specific frequencies or range used
- Information required by coordinator
- The American Hospital Association, American Society for Healthcare Engineering Serves as the Frequency Coordinator
- Modulation scheme used and bandwidth
- Effective radiated power
- Number of transmitters in facility and manufacturer and model numbers
- Name of health care provider
- Transmitter location (coordinates, street address)
- Point of contact for authorized health care provider

Other Wireless Medical Telemetry Frequencies

Wireless medical telemetry is allowed to operate over other frequencies, including the ISM bands (915 MHz, 2450 MHz). The ISM bands were intended for the use of industrial, medical, or scientific products and devices that use RF energy for their function. Examples of these products include microwave ovens, RF-welding equipment, some radars, and medical diathermy. Because few technical restrictions for equipment exist in these bands, and the cost of components for transmissions in these bands have decreased, an increasing amount of communications equipment has migrated to these frequencies. However, the ISM bands, especially the higher bands mentioned above, are rapidly being filled with large numbers of users such as portable phones and wireless LANs. The equipment operating in these bands must be robust and able to withstand significant EMI from the other in-band transmitters. Microwave ovens, for example, are well known to modulate widely over the entire ISM band where they operate and have been seen to interfere (Buffler and Risman, 2000). However, if the equipment is robust enough, it might be able to perform adequately in most environments for use with medical telemetry. Knowing there are risks of EMI with wireless medical telemetry, users must perform their own risk assessment and plan their strategy to design and configure their wireless medical telemetry to minimize the risks of EMI. The FDA recognized the need to address these risks and issued a guidance document to the medical device industry with recommendations to assess and appropriately address these risks including helping the device user community (FDA, 2000).

EMI Risk Assessment for Health care Facilities

With the creation of the WMTS it is possible to significantly reduce the risks associated with wireless patient monitoring. As recommended by the FDA, medical device manufacturers and the user community (primarily hospitals) need to assess their telemetry systems for risks of electromagnetic interference and, if warranted, take appropriate action to reduce that risk. The recommendations to users of these telemetry systems focus on review at the institutional level. The institution must balance the factors of operating, such as the cost of altering or replacing the telemetry system, against the risks of harm for the patients.

One way to frame the decision about altering or replacing medical telemetry is based on a risk model from the American National Standard ANSI/AAMI/ISO 14971:2000 Medical Devices—Application of Risk Management to Medical Devices (ANSI, 2000). Under this model, a stepwise progression is taken to plan, assess, and control the risks for the use of medical devices. This approach can be summarized by the following steps:

- Plan the risk management process
- Perform a risk analysis
- Evaluate the risks, and ways to address these risks
- Take action to mitigate and control the risk
- Put into place a program to monitor EMI incidents and proactively reassess telemetry for changes in transmission or device use

Under this model, the need to address risk is based on the seriousness of the hazard, the likelihood that an adverse event will occur, and the impact on the patient if the adverse event actually occurs. The risks for wireless medical telemetry must be continually reassessed as new hazards may arise or the device may be used in new ways that impact the acceptability of known risks. In the end, each facility must decide how it will address the issue, both now and in the future. Figure 103-5 demonstrates a risk assessment and management process developed specifically for wireless medical telemetry.

Risk Management Planning

At the beginning stage, it is important to establish the responsibilities and scope for the risk management process. Involvement of the appropriate parties in the process is critical to its success. Ideally, the institution's safety committee should have oversight of the risk assessment process and responsibility for implementing the resulting recommendations. In addition, knowledge of radio and communications technology is requisite for the successful risk management process related to wireless medical telemetry. Thus, this expertise must be brought into the process from within the facility (e.g., clinical engineering, telecommunications, information management) or contracted with appropriate EMC experts. The safety committee should designate the point of authority for implementing the spectrum-management program. Such person must have a good working knowledge

Develop Plan to Assess Risk to Wireless Telemetry

1. Assign responsibilities and scope of risk management process, including identification of a point of authority for implementation of spectrum management program.
2. Determine types and numbers of telemetry devices, patient parameters being monitored, device locations, and transmission frequencies used.
3. Identify safety hazards (EMI and patient impact).
4. Define risk acceptability criteria.

Risk Analysis and Evaluation

1. Identify EMI risks.
2. Inventory all radio transmitters (e.g. walkie talkies and wireless communications devices, such as wireless LANs).
3. Determine acceptability of electromagnetic interference risk.

Mitigation and Ongoing Monitoring

1. Analyze options for mitigating risk.
2. Take action to mitigate risk and synchronize and coordinate those actions with spectrum changes timeline.
3. Establish a proactive spectrum management program to manage, monitor, report, and mitigate EMI risks and issues.
4. Establish an education program for caregivers about the potential for EMI, how to report incidents of EMI, and how to react to them.

Figure 103-5 Risk management process for telemetry.

of wireless medical telemetry concerns. Because there is a continual reassessment involved in the process (due to the ongoing changes in medical devices and communications technology) it is highly recommended that the risk assessment and management process include all of the people involved in the purchase, use, and maintenance of telemetry equipment.

Early in the risk assessment planning stage, it is useful to determine the types and numbers of wireless medical telemetry devices, the patient parameters being monitored, device locations, transmission frequencies and number of channels used. The information obtained about the wireless medical telemetry use will be helpful during the risk analysis phase. As described previously in this chapter, wireless medical telemetry can operate in different parts of the spectrum. For this reason, changes in spectrum utilization can pose risks to wireless medical telemetry products operating in the same frequency spectrum but likely will have little or no impact on medical telemetry operating in another part of the spectrum. For example, telemetry operating on channel 37 (608–614 MHz) likely will not be impacted by changes in the ISM band.

The last step in the planning phase is to determine the acceptability of the risk for each health care facility's situation. For example, a tertiary-care facility with a critical cardiac population might have a higher level of concern about interference to the wireless medical telemetry than a community-based hospital. The risk acceptability criteria are a determination of how much interference or loss of wireless patient information is tolerable to the health care facility. These criteria can be categorized to determine the qualitative levels of risk (e.g. occasional, probable, frequent, and certain). Determining the potential safety hazard or impact on patient safety in the event of interference is a prerequisite to determining the risk acceptability criteria. During this step, a decision about what is acceptable to the institution will be used to drive decisions in the risk analysis and evaluation phase.

Risk Analysis and Evaluation

The first step in the risk analysis and evaluation phase is to identify the EMI hazards to wireless telemetry signals. An AHA Task Force (ACCE News, 1998) identified the most immediate potential hazards as changes to the PLMRS, emerging DTV, and another TV broadcast called "low-power television" (LPTV). The LPTV service was established in 1982 by the FCC with the intention of providing opportunities for locally oriented television service on a secondary-frequency user basis. Because of power restrictions on the transmission signals, LPTV is targeted to small localized areas but still may threaten medical telemetry if that telemetry operates on the same frequencies as the LPTV station.

There are other risk factors that can affect all wireless communication systems, including telemetry systems, regardless of the transmission frequency utilized. These risk factors include EMI with the device connected to the patient or the remote monitoring device. The EMI can be a result of other wireless communications transmissions or other electromagnetic disturbances (e.g., AC power problems or electrostatic discharge). All of these sources of electromagnetic disturbances contribute to the potential for medical device EMI, either with the transmission of patient physiological signals or the devices that receive or transmit these signals. Therefore, the risk analysis and evaluation phase should include an inventory of all wireless communications devices used in the health care facility, including transmitters on the roof. (See the AAMI TIR 18-1997 for a thorough explanation of medical device EMI from radio transmitters and how to address this issue. (AAMI, 1997))

The radio transmission frequencies utilized by the wireless telemetry system will determine the applicability of these various hazards for the users. For example, a telemetry system operating in the TV channels in the VHF frequencies typically will not be impacted by the refarming of PLMRS but are likely to be affected by the DTV or LPTV. Analysis of the risks posed by PLMRS changes, DTV, and LPTV involves predicting the

probability of interference from these sources and the potential impact of that interference on patient safety. Applying the ANSI medical-device risk management model to this analysis will help determine the acceptability of the risks (ANSI, 2000).

For wireless telemetry systems that currently are operating in the 450–460 MHz frequency band, the probability of interference increased dramatically in January 2001, when the FCC lifted its freeze on PLMRS refarming for these frequencies. The probability of interference to systems operating in the 460–470 MHz frequencies will likewise increase dramatically in July 2003, when the PLMRS is refarmed for these frequencies as well. Although it is difficult to quantify the growth rate of PLMRS use following the lifting of these freezes, there likely will be up to four times more users of the new narrow channels. Because PLMRS users are typically mobile sources, interference with the wireless medical telemetry likely will be intermittent as well as difficult to track and identify. The likelihood of experiencing interference from PLMRS in part depends on how many of these transmitters are used in the vicinity of the medical telemetry system. There likely will be more PLMRS transmitters in use in densely populated areas. Therefore, the risk of interference for wireless medical telemetry currently transmitting on the PLMRS frequencies is more likely in urban areas that have a concentration of commercial PLMRS transmitters. Given these various considerations, the probability of continued or intermittent interference for medical telemetry in the PLMRS frequencies is at least occasional, but more likely is probable or frequent. Furthermore, the resultant risk of injury to the patient due to a disruption in the monitoring is likely at a critically unacceptable level. Thus, actions must be taken to mitigate the interference risk for most of these systems operating at 450–470 MHz frequencies.

The probability for interference to medical telemetry from DTV in different locales can be predicted through review of DTV information posted on the FCC web site (<http://www.fcc.gov/>) and following FCC announcements and petitions by local TV broadcasters. In general, the local broadcasters are supposed to notify any affected hospitals in advance of beginning DTV transmissions. If a DTV begins station broadcast on a TV channel utilizing the same frequencies as a local telemetry system, then the telemetry system will be rendered inoperable over the entire 6 MHz of the DTV channel (Figure 103-2 shows that the DTV signal takes up virtually all of the particular TV channel frequency band). For this situation, the risk of interference with the wireless medical telemetry signal seems more certain, and the resultant risk of injury to a patient is at a critically unacceptable level.

LPTV broadcasters are also affected by DTV, and must migrate to different vacant TV channels as the DTV broadcasts begin. Thus, the changes brought about by DTV will cascade down to LPTV and possibly affect medical telemetry. When the LPTV changes frequencies, it may produce interference to the local wireless telemetry, even though the clinical telemetry user has made efforts to coordinate with the DTV changes. However, by comparing a list of DTV stations in the area with a list of LPTV stations in the user's local area (found through the FCC website, <http://www.fcc.gov/mmb/vsd/lp/lp.html>), the reader can determine which LPTV stations will have to change because of the DTV broadcasts. Medical telemetry users should then contact and coordinate with the LPTV broadcaster to plan for an orderly migration to new frequencies that minimize the risks to patients. If there is a direct conflict among the new LPTV frequencies and the frequencies used by the existing medical telemetry, the risk analysis and evaluation for the telemetry is very similar to that for DTV. Because additional LPTV frequency designations are anticipated in the future, continued vigilance in this area is necessary.

Wireless communications transmitting on one of the ISM bands have a recognized potential for interference and thus use technologies to protect themselves from interference. Currently, there is great debate within the clinical engineering community about how successful these protection mechanisms are in ensuring the reliability of ISM medical telemetry systems and their ability to co-exist with other ISM frequency users. At best, the probability for interference in the ISM bands will remain a concern as new ISM technologies emerge and present interoperability issues. When utilizing an ISM band telemetry system, the user must continually manage all of the communications technologies that exist within the health care facility to decrease the potential for interference.

Under the ANSI risk management model, it is necessary to estimate how often the interference to the ISM wireless medical telemetry might occur. As the congestion of unlicensed secondary users in the ISM band increases, the risk of interference grows. For the ISM band telemetry system, the probability of interference could be remote, occasional, probable, or frequent; but as congestion in these bands increase, so too will the probability of interference. The risk of injury to the patient still can be considered as critical, based on the use of telemetry, and hence this risk will need to be mitigated. As the probability of interference increases, the risk likely will become unacceptable.

The potential for interference to wireless medical telemetry from other wireless communications systems used within the facility will be dependent on the relative transmitter output power levels and frequency, as well as the separation of the transmitter from the medical device. An obvious conflict to wireless telemetry systems operating in the PLMRS is posed by use of two-way radios that also operate in this band. Similarly, wireless LANs operating in the ISM bands may pose a risk to wireless telemetry systems that transmit in the same ISM bands. As part of the risk analysis and evaluation, each type of wireless communication device in the facilities' inventory must be analyzed and evaluated. A thorough inventory of radio transmitters must also include both fixed, (e.g., TV) and mobile (e.g., police fire, and commercial) radio transmitters that operate in the general geographic location. As mentioned above, the changes to the PLMRS, DTV, and LPTV are outside the control of the health care facility but must be taken into account when performing the risk assessment and evaluation. Equipment that works today may pose high risks tomorrow as the radio spectrum continues to change.

Mitigation and Ongoing Monitoring

Once the level of risk to the telemetry system is identified, appropriate action must be taken to mitigate or reduce that risk. Mitigation may involve simply retuning medical telemetry transmitters to other frequencies. For example, if a small installation of VHF TV channel frequency medical telemetry is at risk of interference from a DTV station,

there may be sufficient spectrum available at a different, vacant, TV channel frequency to retune the telemetry transmitters and thus mitigate the risk. Such an approach can be adequate for a time, but eventually the use of the radio airways will be such that the facility will be left with little alternative but to migrate to a spectrum offering more protection and lower risks. For larger installations in a similar situation, there might be insufficient vacant frequencies to allow continued use of these TV channel frequencies, and thus migration to another spectrum (e.g., WMTS) will be necessary. The actions taken to mitigate the risks for interference will need to be synchronized and coordinated with the spectrum changes that drove the EMI risk decision. For example, telemetry systems operating in the 460–470 MHz frequency band will need to migrate prior to July 2003, and telemetry systems operating in a band to be used by a DTV station will need to migrate prior to the DTV test broadcasts.

A program for ongoing monitoring and mitigation of EMI issues will become more important as hospitals, and the society at large, embrace wireless technology. Such a program must facilitate and continuously coordinate for the reliable functioning of all medical equipment including telemetry. A proactive and continuous spectrum management program will include the following:

- A point of authority for maintaining reliable wireless communications,
- A policy for reporting and evaluating incidents of interference
- An inventory of all existing transmitters used on the premises, including those transmitters that are allowed to reside on the hospital's roof (or anywhere close to the health care facility) for a fee
- An assessment of interoperability of medical device (including wireless telemetry) prior to acquisition of additional wireless technology
- Facilitating the integration of wireless technology through proactive management of all radio transmitters in or around the health care facility
- Methods for minimizing interference
- Reporting interference incidents and issues to the point of authority for such matters
- Reporting patient injury or death related to device malfunction as required under the Medical Device Reporting (MDR) regulation (Part 803 of Title 21, Code of Federal Regulations (CFR)) pursuant to the Safe Medical Devices Act of 1990.

Based on an increased understanding of EMI and its impact on medical equipment functioning, hospital personnel should pay more attention to interference risks than they have in the past. Clinical engineers and hospital personnel in general need to begin proactively addressing incidents of interference. This will involve education of the caregivers so that they will report all medical equipment problems to the clinical engineering department for thorough investigation. Ideally, all patient caregivers will be familiar with the policy for reporting and evaluating incidents of interference. A continuing education effort will likely be needed, to make staff members aware of the changes and to keep them apprised of developments in this rapidly evolving area. Clinical engineering personnel must use the reported information to assess the potential impact of RF interference in reported situations based on the inventory of transmitters used in the hospital. Where interference is identified, action must be taken to prevent recurrence.

When considering acquisition of new wireless technology, the ability of that technology to operate with the existing base of wireless technology should be assessed. This ability can be determined based on a review of the complete inventory of wireless equipment with the incumbent vendor and requiring the vendor to qualify that their new equipment will work with the present systems and in the intended use environment.

Establishment of a point authority for implementing the wireless communications and telemetry management program is highly recommended because there is an appetite in the medical community for wireless technology, which is expected to grow rapidly. Recommended responsibilities for this entity include maintenance of the wireless equipment inventory, rigorous evaluation of reports of potential interference, tracking and trending incidents of interference, evaluation of the interoperability of new equipment, and recommendations for mitigating interference risks.

A survey performed by the AHA Wireless Medical Telemetry Task Force revealed that a wide variety of parameters would be monitored via telemetry if the technology to do so were available. In recognition of these needs, the definition and service rules adopted in the creation of WMTS allows for innovative use. Therefore, the ongoing monitoring phase of the risk management process will include a re-evaluation of the risk based on the changes in the intended use of telemetry. For example, if telemetry were used to monitor fetal heart rate on an ambulating expectant mother, and that monitoring indicated fetal-heart decelerations, the level of risk to the patient could be higher than for a typical ambulatory cardiac patient.

Conclusions

The use of wireless medical telemetry is expected to grow in the coming years as the population ages and the wireless technology becomes more common and less expensive. At the same time, the risks of EMI with these vital signals are increasing for users of the older, secondary frequencies as these frequencies are being changed by the FCC to accommodate more commercial use. Indeed, the changes have begun with the DTV reallocations and the announcement of the changes to the PLMRS—both frequency bands that have been widely used for medical telemetry. Hospital users of wireless telemetry must immediately begin to assess their devices for the risks of EMI and must make changes to address the increased risks for EMI. Recommendations to reduce the risks of EMI with wireless medical telemetry include switching to the new WMTS frequencies where the medical signals are afforded protections and the oversight of a frequency coordinator. With appropriate assessment and proper planning, the EMI risks to wireless medical telemetry should be dramatically reduced, both now and into the future.

Health Insurance Portability and Accountability Act (HIPAA) and Its Implications for Clinical Engineering

Stephen L. Grimes

Senior Consultant and Analyst, GENTECH
Saratoga Springs, NY

What is a chapter on the Health Insurance Portability and Accountability Act (HIPAA) doing in a handbook on clinical engineering? This is an understandable question! Judging solely by the name, most readers would understandably expect to find a discussion on health insurance and finance. But scratch the surface and you will actually find the most significant piece of health care legislation since Medicare was signed into law in 1965. Look further into the labyrinth of legislation and associated rules, and you will find that HIPAA introduces standards that will require broad changes in our health care operations as well in as the way we adopt and implement technology.

The Origins of HIPAA

HIPAA (also known as Public Law 104-191 or the Kassebaum-Kennedy bill) was signed into law by President Clinton in 1996 (for more about Public Law 104-191 see <http://www.cms.hhs.gov/hipaa/hipaa2/general/background/pl104191.asp>). The original law was conceived during the first Bush Administration and later was included in the Clinton Administration's Health Care Reform Initiative. As the name implies, HIPAA was originally intended to provide a means for consumers to maintain their health insurance coverage regardless of their employment situation. As happens with most legislation between conception and passage, peripheral provisions were added to the bill. Arguably, the most significant of these was called the "administrative simplification provision" (Figure 104-1).

Administrative simplification was added to HIPAA to address a problem brought to Congress's attention in the early 1990s. In 1991, the *New England Journal of Medicine* published an article reporting that 19 to 24 cents of every dollar spent in the U.S. on health care went toward "administrative" costs (Woolhandler and Himmelstein, 1991), as compared with 11% in Canada and 7% in most of Europe (Figure 104-2a). These administrative costs were due in large part to industry inefficiencies: 70% of data being manually keyed into industry computers were output from other computers; at the same time, the industry was bogged down in manual filing, photocopying, faxing, telephoning, and mailing (Moynihan, 2003). The problem would worsen. In 1988, the U.S. spent \$558 billion on health care, or 11% of its gross domestic product (GDP) (Heffler et al., 2003). By 2001, those expenditures had risen to \$1,425 billion, or 14.1% of the GDP. By 2012, they are estimated to rise further to \$3.1 trillion, or 17.7% of the GDP (Figure 104-2b). In 1994, Congress was made aware of at least one possible solution to the problem of escalating health care costs. That year, a report prepared by a respected industry group, the Workgroup for Electronic Data Interchange (WEDI), claimed that the health care industry could save \$73 billion annually if it adopted electronic data interchange (EDI) for most administrative and financial transactions, as many other U.S. industries had already done (Duncan et al, 2001). Congress recognized that the nature of electronic transactions made industry vulnerable in ways unlike their paper counterparts and added requirements for privacy and security to the administrative simplification provision of HIPAA.

As the law was written, the Department of Health and Human Services (HHS) was to be responsible for formulating the actual Transaction and Code Sets (TCS) rule and the security rule. The law directed HHS to avail itself of the expertise of various industry organizations, including the National Committee on Vital and Health Statistics (NCVHS) when developing these rules. Within HIPAA, Congress gave itself 36 months to prepare the privacy rule, with that responsibility falling back to HHS only if Congress were to fail to complete the task in the allotted time frame. It did fail to do so and HHS ultimately took on the task of formulating the privacy rule, too.

According to law, HHS was to prepare a draft for each rule and publish it as a notice of proposed rule making (NPRM) for comment in the *Federal Register*. The public then would have 60 days in which to comment, after which HHS would prepare the final rule,

taking those comments into consideration. Once the final rule was published in the *Federal Register*, there would be a 60-day review, followed by a 24-month grace period before the rule would take effect (except for small health plans, which were given an additional 12 months to comply). Congress's plan had been to have HIPAA's TCS, privacy, and security provisions in place by the year 2000. However, Congress provided little funding for HHS to begin the process, and the Y2K issue was quickly consuming industry resources (see Chapter 105). Barring other significant delays, the last of the major HIPAA rules will be in effect by April of 2005.

Overview of HIPAA's Administrative Simplification Provisions: TCS, Privacy, and Security Rules

The three major rules associated with administrative simplification are transaction and code sets, privacy, and security. HHS finalized the rules over nearly three years, beginning with TCS in October 2000, and ending with security in April 2003. A brief overview of each of the rules follows:

Transaction and Code Sets (TCS) Rule

The compliance date for the Transaction and Code Sets (TCS) Rule was October 16, 2003. A one-year extension applies to small (i.e., >\$5M annual revenue) health plans and to those that have applied for a one-year extension (under ASCA). Covered entities (other than small health plans) that did not apply for one-year extension before October 15, 2002 needed to be compliant by October 16, 2002. The Enforcing Authority is the HHS Centers for Medicare and Medicaid Services (CMS).

The TCS rule is the heart of administrative simplification and the source of any projected cost savings. The rule calls for the adoption of standardized transactions and code sets by health plans, health care clearinghouses, and health care providers who transmit health information in electronic form in connection with any of the transactions defined below.

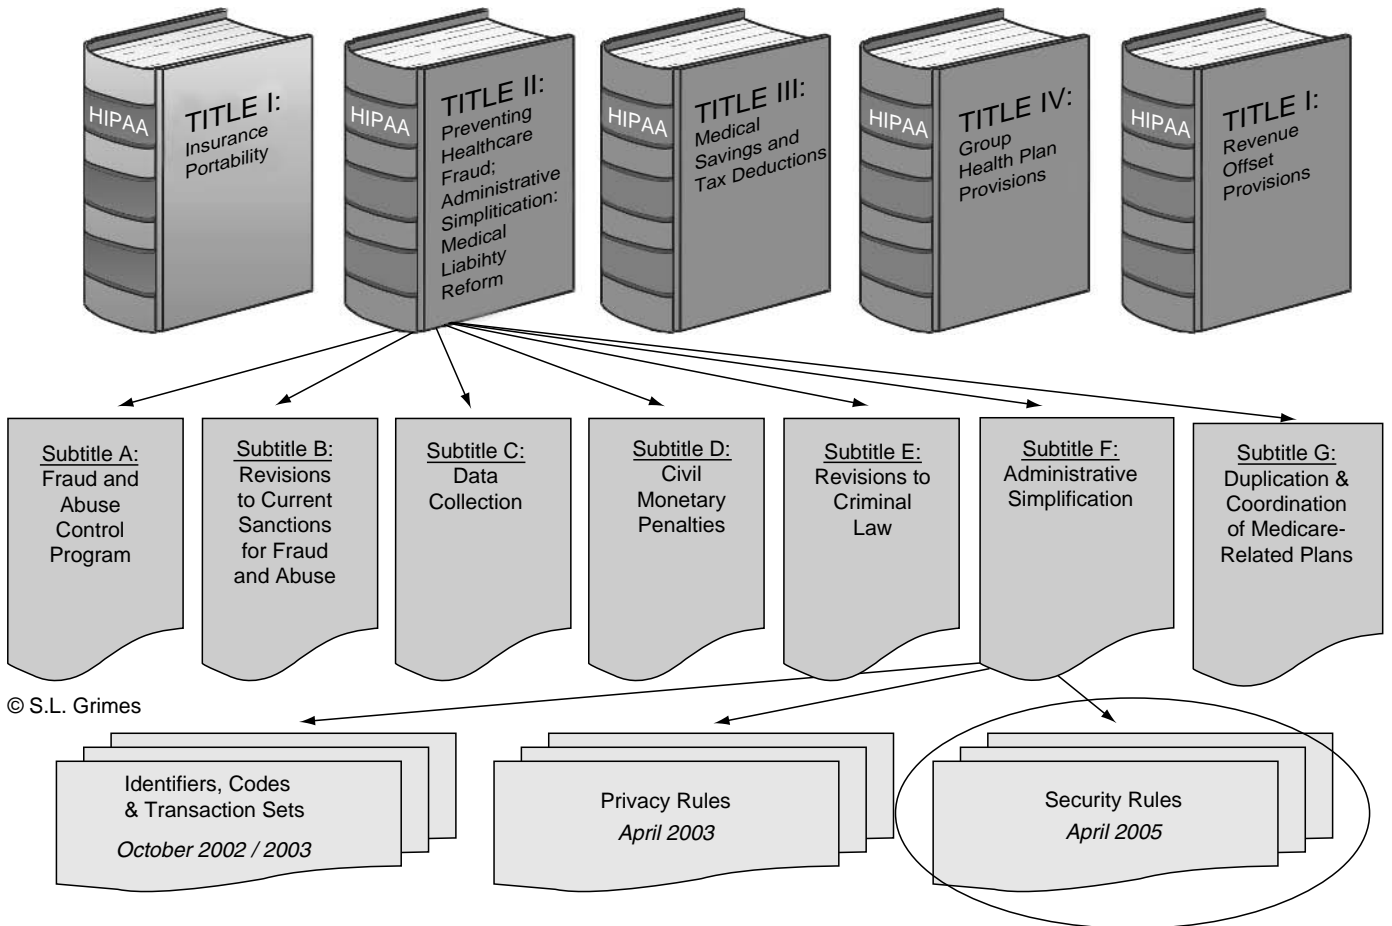

The standardized transactions are defined by American National Standards Institute (ANSI) X12N specifications and address the following:

- Premium payment /remittance
- Health care claim/encounter
- Plan enrollment /De-enrollment
- Eligibility for health plan
- Coordination of benefits
- Claim payment/remittance advice
- Health care claim status
- Referral Certification and Authorization
- Health care claim attachment (under development~HL7 records)
- First report of injury

The standard code sets are taken from versions defined by the following:

- International Classification of Diseases (ICD)
- AMA's Current Procedural Terminology (CPT)
- HHS's National Drug Codes (NDC)
- Health Care Finance Administration's Common Procedure Coding System (HCPCS)
- ADA's Codes on Dental Procedures and Nomenclature
- National Council for Prescription Drug Programs (NCPDP)

*Estimated

Figure 104-2b Trend in United States healthcare expenditures.

These standardized codes address the following:

- Diagnoses
- Treatments
- Procedures
- Tests
- Services
- Drugs
- Supplies/equipment

Privacy Rule

The compliance date for this rule was April 14, 2003, except for small health plans, which have an additional 12-month grace period. The enforcing authority is the HHS Office for Civil Rights (OCR).

The privacy rule covers health plans, health care clearinghouses, and health care providers who transmit any health information electronically. The rule requires these covered entities to develop and implement policies and procedures as follows:

- Limit access to a patient's individually identifiable health information (IIHI) in any form (i.e., electronic, written, oral) to only that information required by those who have a need based on their involvement in treatment, payment, or health care operations (TPO) unless the patient has explicitly authorized broader access.
- Give patients the right to access to their medical records, to request corrections to those records, and the right to know who has accessed those records.
- Compel business associates (who may, as a consequence of their work, access IIHI) to adopt privacy policies and procedures consistent with the requirements of this rule.
- Provide appropriate sanctions for any person or business associate who inappropriately obtains or uses a patient's IIHI.

Security Rule

The compliance date for the security rule is April 21, 2005, except for small health plans, which have an additional 12-month grace period. The enforcing authority is the HHS Centers for Medicare and Medicaid Services (CMS).

The security rule also covers health plans, health care clearinghouses, and health care providers who transmit health information to any of the covered transactions electronically. The rule applies to electronic protected health information (ePHI) that is transmitted or maintained in electronic media, although HHS warns "that standards for the security of all health information or protected health information in non-electronic form may be proposed at a later date."

The rule requires covered entities to ensure the confidentiality, integrity, and availability of their ePHI by establishing the following:

- **Administrative Safeguards**
 - Security management processes that include an effective risk analysis and risk management program
 - Workforce security (e.g., authorization, clearance, and sanctions)
 - Security incident (e.g., response and reporting)
 - Education and training of workforce on security issues
 - Contingency plans (e.g., criticality analysis, back-up, and disaster recovery)
 - Evaluation of security program effectiveness
 - Business-associate contracts
- **Physical Safeguards**
 - Facility access (e.g., contingency, security, access control, and maintenance)
 - Workstation use and security
 - Device and media controls (e.g., disposal, backup, and accountability)
- **Technical Safeguards**
 - Access controls (e.g., user identification, encryption, and emergency access)
 - Audit controls (e.g., tracking access activity)
 - Integrity (e.g., authentication of ePHI)
 - Transmission security (integrity controls and encryption)
- **Organizational Requirements**
 - Business associate contracts
- **Policies, Procedures and Documentation Requirements**
 - Policies and procedures necessary to comply with standards
 - Documentation (e.g., maintain records of compliance actions, activities, or assessments)

Failure to comply with the administrative simplification provisions of HIPAA carries the risk of substantial civil and criminal penalties. There are civil fines of up to \$100 per violation and up to a maximum of \$25,000 per year possible for identical violations. Because any failure to comply could involve violations of multiple standards, the actual total penalties per incident could far exceed the individual maximums. Criminal penalties range from \$50,000 and one year in jail for anyone who obtains protected health information, to \$50,000 and 5 years in jail for anyone who obtains protected health information under false pretenses, to \$250,000 and 10 years in jail for anyone who obtains protected health information with the intent to use it for commercial advantage, personal gain, or malicious harm.

HIPAA's Effect on Clinical Engineering

Over the next several years, HIPAA compliance efforts will be a high-priority item on the agendas of virtually all of the 1.2 million providers of health care in the US. These providers include hospitals, laboratories, imaging and surgery centers, clinics, pharmacies, physician practices, and other clinical practices.

HIPAA will consume a significant portion of the hospital's resources. It is estimated that HIPAA will cost hospitals over \$43 billion to implement (Lageman and Melick, 2000), compared with the \$8.5 billion that hospitals spent addressing the Y2K problem (Marietti, 1999).

The strategic interests of provider organizations are closely aligned with HIPAA compliance. Each operational unit within the provider organization (including clinical engineering) is obliged to use any resources that are appropriate and available to assist their organization in achieving compliance. While clinical engineering shares some of the overall HIPAA compliance burden with other operational units, it will have the greatest impact in compliance with the security rule.

HIPAA's security rule was conceived to protect the integrity, availability and confidentiality of health information or data associated with a patient. This includes data in medical and billing records found in provider information systems. It also includes diagnostic and therapeutic data found in biomedical devices and clinical information systems. In fact, biomedical devices and systems used by health care providers represent a substantial and growing area of risk with respect to HIPAA security issues. The total quantity of biomedical devices and systems in a typical hospital may be 300 to 400% more than the number of IT devices and systems in that same hospital. HIPAA-affected systems in both the IT and biomedical inventories can represent a substantial portion of that hospital's total systems. There are two major trends contributing to the significance of the biomedical technology-related risk:

1. Biomedical devices and systems are being designed and operated as special purpose computers with more automated features. This results in increasing amounts of health data being collected, analyzed, and stored in these devices.
2. There has been a rapidly growing integration and interconnection of disparate biomedical and information technology devices and systems where health information is exchanged.

While biomedical technology represents a substantial repository of health information, these devices and systems are often overlooked by what is frequently an IT-centric approach to HIPAA security.

Security is an issue for biomedical technology because any compromise in ePHI integrity or availability can lead to the improper diagnosis or therapy for a patient. Delayed or inappropriate treatment can result in harm, or even death. Any compromise in confidentiality can compromise patient privacy and may result in financial loss to the patient and/or the provider organization.

To successfully address HIPAA security, clinical engineers must be prepared to adopt a different mindset. Clinical engineers must approach the management of technology from a security standpoint, recognizing that ensuring the integrity and availability (as well as the confidentiality) of health information is the heart of an effective technology management program.

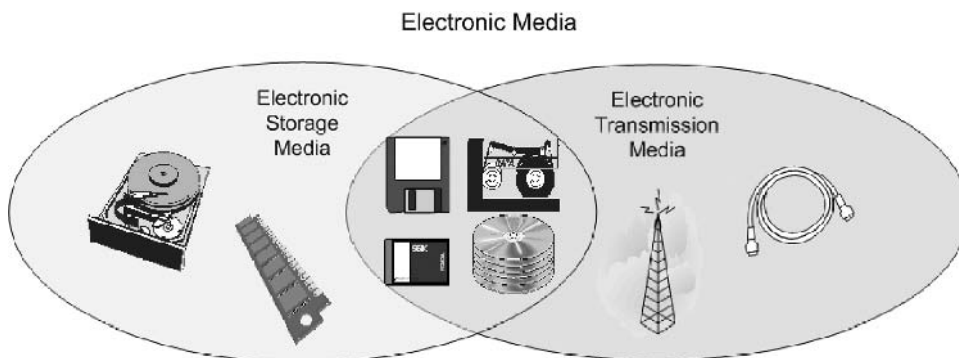

A Closer Look at the Security Rule

HIPAA's security rule was designed to ensure the integrity, availability, and confidentiality of all electronic protected health information (ePHI) the provider creates, receives, maintains, or transmits. For purposes of the security rule, integrity, availability, and confidentiality are defined as follows:

- **Integrity:** Data have not been altered or destroyed in an unauthorized manner
- **Availability:** Data are accessible and useable upon demand by an authorized user
- **Confidentiality:** Data are not made available nor disclosed to an unauthorized person

A few other key definitions associated with the Security Rule include the following:

- **Electronic Protected Health Information (ePHI)** is Individually Identifiable Health Information (IIHI) that is transmitted or maintained in electronic media.
- **Individually Identifiable Health Information (IIHI)** is information that is a subset of health information, including demographic information collected from an individual, and
 1. is created or received by the healthcare provider and
 2. relates to the past, present or future health or condition of an individual; the provision of care to an individual and
 - a. identifies the individual
 - b. with respect to which there is a reasonable basis to believe the information could be used to identify the individual
- **Electronic media (Figure 104-3)** is
 - **Storage media** including
 - Memory devices
 - Removable/transportable digital memory medium (e.g., magnetic tape or disk, optical disk, digital memory card)
 - **Transmission media** used to exchange information already in electronic storage media including
 - Internet, Extranet
 - Leased and dial-up lines

- Private networks
- Physical movement of removable/transportable electronic storage media

The security rule was written to be flexible. Providers are permitted to use any security measures that enable them to reasonably and appropriately implement the requirements. In selecting the security measures to use, the providers must take into account the following:

- Size, complexity, and capabilities of the organization
- Technical infrastructure, hardware, and software security capabilities of the organization
- Costs of security measures
- Probability and criticality of potential risks to the confidentiality, integrity, and availability of ePHI

The security rule presents its requirements as a series of standards. Standards are required policies, practices, services, or systems that the provider must implement in order to be in compliance with the security rule. The security rule also presents a series of implementation specifications associated with most standards. Implementation specifications are guidelines as to ways to meet a particular standard. The security rule classifies the provided implementation specifications as either “required” or “addressable.” A provider must use “required” implementation specifications to meet their respective standards. A provider should use “addressable” implementation specifications to meet their respective standards unless the provider can demonstrate that it meets the standard with a reasonable and appropriate alternative. Factors justifying the use of alternate schemes to meet standards include the results of risk analyses, risk mitigation strategies, the existence of any security measures already in place, and the cost of implementation. When alternate schemes are taken, the decision process and the chosen implementation methods must be well documented.

The security rules standards and implementation specifications are divided into the following categories

1. Administrative safeguards, which include:
Documented, formal measures (including policies and procedures) to manage the selection, development, and execution of security measures to protect electronic data and the conduct of the workforce in relation to the protection of that electronic data
2. Physical safeguards, which include:
Measures to physically protect systems storing or transmitting health data and related buildings and equipment from:

- Natural and environmental hazards (e.g., fire and flood)
 - Intrusion (i.e., use of locks, keys, and administrative measures to control access)
3. Technical safeguards, which include:
Technical measures to protect systems storing or transmitting health data in the following ways:
 - Protecting information access
 - Controlling and monitoring information access and system activity
 - Verifying data integrity
 - Ensuring availability
 - Ensuring transmission security
 4. Organizational requirements, including:
Use of business associate agreements to compel agents, subcontractors, vendors, consultants, and others who may have access to electronic protected health information to employ appropriate security measures to safeguard ePHI
 5. Policies/procedures and documentation requirements, including:
Measures to ensure that policies and procedures comply with the standards and implementation specifications of the security rule and that all actions, activities, and assessments conducted with respect to these requirements are documented.

A detailed matrix of security rule standards and implementation specifications is provided in Table 104-1.

The Compliance Process

Security Management

HIPAA’s security rule requires providers to formulate a security management program and integrate risk analysis and management elements into that process (see Figure 104-4).

To establish an effective security management program, each organization must first assign a security official who will have the overall responsibility and authority to develop, implement, and manage the organization’s security measures. After assigning a security official, the provider must progress through the five levels (Figure 104-5) of a security plan in order to achieve the goal of a truly effective security program. These levels include the following:

- Level 1** Develop necessary policies per security rule’s standards.
Each provider organization must establish a set of policies that are designed to meet the specific requirements of the security rule but are also designed to fit the character (i.e.,

Table 104-1 HIPAA Final Security Rule—Standards and Implementation Specifications Matrix

<i>Administrative Safeguards</i>		
<i>Sections</i>	<i>Standards</i>	<i>Implementation Specifications</i>
164.308(a)(1)	(i) Security management process. Implement policies and procedures to prevent, detect, contain, and correct security violations	(A) Risk analysis (REQUIRED). Conduct an accurate and thorough assessment of the potential risks and vulnerabilities to the confidentiality, integrity, and availability of electronic protected health information held by the covered entity. (B) Risk management (REQUIRED). Implement security measures sufficient to reduce risks and vulnerabilities to a reasonable and appropriate level to comply with §164.306(a). (C) Sanction policy (REQUIRED). Apply appropriate sanctions against workforce members who fail to comply with the security policies and procedures of the covered entity. (D) Information system activity review (REQUIRED). Implement procedures to regularly review records of information system activity, such as audit logs, access reports, and security incident tracking reports.
164.308(a)(2)	(i) Assigned security responsibility. Identify the security official who is responsible for the development and implementation of the policies and procedures required by this subpart for the entity	(REQUIRED)
164.308(a)(3)	(i) Workforce security. Implement policies and procedures to ensure that all members of its workforce have appropriate access to electronic protected health information, as provided under paragraph (a)(4) of this section, and to prevent those workforce members who do not have access under paragraph (a)(4) of this section from obtaining access to electronic protected health information . . .	(A) Authorization and/or supervision (ADDRESSABLE). Implement procedures for the authorization and/or supervision of workforce members who work with electronic protected health information or in locations where it might be accessed. (B) Workforce clearance procedure (ADDRESSABLE). Implement procedures to determine that the access of a workforce member to electronic protected health information is appropriate. (C) Termination procedures (ADDRESSABLE). Implement procedures for terminating access to electronic protected health information when the employment of a workforce member ends or as required by determinations made as specified in paragraph (a)(3)(ii)(B) of this section.
164.308(a)(4)	(i) Information access management. Implement policies and procedures for authorizing access to electronic protected health information that are consistent with the applicable requirements of subpart E of this part. . . .	(A) Isolating health care clearinghouse functions (REQUIRED). If a health care clearinghouse is part of a larger organization, the clearinghouse must implement policies and procedures that protect the electronic protected health information of the clearinghouse from unauthorized access by the larger organization. (B) Access authorization (ADDRESSABLE). Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. (C) Access establishment and modification (ADDRESSABLE). Implement policies and procedures that, based upon the entity’s access authorization policies, establish, document, review, and modify a user’s right of access to a workstation, transaction, program, or process.
164.308(a)(5)	(i) Security awareness and training. Implement a security awareness and training program for all members of its workforce (including management) . . .	(A) Security reminders (ADDRESSABLE). Periodic security updates. (B) Protection from malicious software (ADDRESSABLE). Procedures for guarding against, detecting, and reporting malicious software. (C) Log-in monitoring (ADDRESSABLE). Procedures for monitoring log-in attempts and reporting discrepancies. (D) Password management (ADDRESSABLE). Procedures for creating, changing, and safeguarding passwords.
164.308(a)(6)	(i) Security incident procedures. Implement policies and procedures to address security incidents . . .	Response and Reporting (REQUIRED). Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity; and document security incidents and their outcomes.

Continued

Table 104-1 HIPAA Final Security Rule—Standards and Implementation Specifications Matrix—Cont'd

<i>Administrative Safeguards</i>		
<i>Sections</i>	<i>Standards</i>	<i>Implementation Specifications</i>
164.308(a)(7)	(i) Contingency plan. Establish (and implement as needed) policies and procedures for responding to an emergency or other occurrence (for example, fire, vandalism, system failure, and natural disaster) that damages systems that contain electronic protected health information....	(A) Data backup plan (REQUIRED). Establish and implement procedures to create and maintain retrievable exact copies of electronic protected health information. (B) Disaster recovery plan (REQUIRED). Establish (and implement as needed) procedures to restore any loss of data. (C) Emergency mode operation plan (REQUIRED). Establish (and implement as needed) procedures to enable continuation of critical business processes for protection of the security of electronic protected health information while operating in emergency mode. (D) Testing and revision procedures (ADDRESSABLE). Implement procedures for periodic testing and revision of contingency plans. (E) Applications and data criticality analysis (ADDRESSABLE). Assess the relative criticality of specific applications and data in support of other contingency plan components.
164.308(a)(8)	(i) Evaluation. Perform a periodic technical and non-technical evaluation, based initially upon the standards implemented under this rule and subsequently, in response to environmental or operational changes affecting the security of electronic protected health information, that establishes the extent to which an entity's security policies and procedures meet the requirements of this subpart.	(REQUIRED)
164.308(b)	(1) Business associate contracts and other arrangements. A covered entity, in accordance with §164.306, may permit a business associate to create, receive, maintain, or transmit electronic protected health information on the covered entity's behalf only if the covered entity obtains satisfactory assurances, in accordance with §164.314(a) that the business associate will appropriately safeguard the information. (2) This standard does not apply with respect to (i) The transmission by a covered entity of electronic protected health information to a health care provider concerning the treatment of an individual. (ii) The transmission of electronic protected health information by a group health plan or an HMO or health insurance issuer on behalf of a group health plan to a plan sponsor, to the extent that the requirements of §164.314(b) and §164.504(f) apply and are met; or (iii) The transmission of electronic protected health information from or to other agencies providing the services at §164.502(e)(1)(ii)(C), when the covered entity is a health plan that is a government program providing public benefits, if the requirements of §164.502(e)(1)(ii)(C) are met. (3) A covered entity that violates the satisfactory assurances it provided as a business associate of another covered entity will be in noncompliance with the standards, implementation specifications, and requirements of this paragraph and §164.314(a)...	Written contract or other arrangement (REQUIRED). Document the satisfactory assurances required by paragraph (b)(1) of this section through a written contract or other arrangement with the business associate that meets the applicable requirements of §164.314(a).
<i>Physical Safeguards</i>		
<i>Sections</i>	<i>Standards</i>	<i>Implementation Specifications</i>
164.310(a)	(1) Facility access controls. Implement policies and procedures to limit physical access to its electronic information systems and the facility or facilities in which they are housed, while ensuring that properly authorized access is allowed. . . .	(i) Contingency operations (ADDRESSABLE). Establish (and implement as needed) procedures that allow facility access in support of restoration of lost data under the disaster recovery plan and emergency mode operations plan in the event of an emergency. (ii) Facility security plan (ADDRESSABLE). Implement policies and procedures to safeguard the facility and the equipment therein from unauthorized physical access, tampering, and theft. (iii) Access control and validation procedures (ADDRESSABLE). Implement procedures to control and validate a person's access to facilities based on their role or function, including visitor control, and control of access to software programs for testing and revision. (iv) Maintenance records (ADDRESSABLE). Implement policies and procedures to document repairs and modifications to the physical components of a facility which are related to security (for example, hardware, walls, doors, and locks). (REQUIRED)
164.310(b)	Workstation use. Implement policies and procedures that specify the proper functions to be performed, the manner in which those functions are to be performed, and the physical attributes of the surroundings of a specific workstation or class of workstation that can access electronic protected health information...	
164.310(c)	Workstation security. Implement physical safeguards for all workstations that access electronic protected health information, to restrict access to authorized users. . . .	(REQUIRED)
164.310(d)	(1) Device and media controls. Implement policies and procedures that govern the receipt and removal of hardware and electronic media that contain electronic protected health information into and out of a facility, and the movement of these items within the facility. . .	(i) Disposal (REQUIRED). Implement policies and procedures to address the final disposition of electronic protected health information, and/or the hardware or electronic media on which it is stored. (ii) Media re-use (REQUIRED). Implement procedures for removal of electronic protected health information from electronic media before the media are made available for re-use. (iii) Accountability (ADDRESSABLE). Maintain a record of the movements of hardware and electronic media and any person responsible therefore. (iv) Data backup and storage (ADDRESSABLE). Create a retrievable, exact copy of electronic protected health information, when needed, before movement of equipment.

Table 104-1 HIPAA Final Security Rule—Standards and Implementation Specifications Matrix—Cont'd

<i>Technical Safeguards</i>		
<i>Sections</i>	<i>Standards</i>	<i>Implementation Specifications</i>
164.312(a)	(1) Access control. Implement technical policies and procedures for electronic information systems that maintain electronic protected health information to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4)....	(i) Unique user identification (REQUIRED). Assign a unique name and/or number for identifying and tracking user identity. (ii) Emergency access procedure (REQUIRED). Establish (and implement as needed) procedures for obtaining necessary electronic protected health information during an emergency. (iii) Automatic logoff (ADDRESSABLE). Implement electronic procedures that terminate an electronic session after a predetermined time of inactivity. (iv) Encryption and decryption (ADDRESSABLE). Implement a mechanism to encrypt and decrypt electronic protected health information.
164.312(b)	Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information...	(REQUIRED)
164.312(c)	(1) Integrity. Implement policies and procedures to protect electronic protected health information from improper alteration or destruction	(2) Mechanism to authenticate electronic protected health information (ADDRESSABLE). Implement electronic mechanisms to corroborate that electronic protected health information has not been altered or destroyed in an unauthorized manner.
164.312(d)	Person or entity authentication. Implement procedures to verify that a person or entity seeking access to electronic protected health information is the one claimed...	(REQUIRED)
164.312(e)	(1) Transmission security. Implement technical security measures to guard against unauthorized access to electronic protected health information that is being transmitted over an electronic communications network.	(i) Integrity controls (ADDRESSABLE). Implement security measures to ensure that electronically transmitted electronic protected health information is not improperly modified without detection until disposed of. (ii) Encryption (ADDRESSABLE). Implement a mechanism to encrypt electronic protected health information whenever deemed appropriate.
<i>Organizational Requirements</i>		
<i>Sections</i>	<i>Standards</i>	<i>Implementation Specifications</i>
164.314(a)	(1) Business associate contracts or other arrangements ... (i) The contract or other arrangement between the covered entity and its business associate required by §164.308(b) must meet the requirements of paragraph (a)(2)(i) or (a)(2)(ii) of this section, as applicable. (ii) A covered entity is not in compliance with the standards in §164.502(e) and paragraph (a) of this section if the covered entity knew of a pattern of activity or practice of the business associate that constituted a material breach or violation of the business associate's obligation under the contract or other arrangement, unless the covered entity took reasonable steps to cure the breach or end the violation, as applicable, and, if such steps were unsuccessful: (A) Terminated the contract or arrangement, if feasible; or (B) If termination is not feasible, reported the problem to the Secretary	(i) Business Associate Contracts (REQUIRED). The contract between a covered entity and a business associate must provide that the business associate will – (A) Implement administrative, physical, and technical safeguards that reasonably and appropriately protect the integrity, and availability of the electronic protected health information that it creates, receives, maintains, or transmits on behalf of the covered entity as required by this subpart.; (B) Ensure that any agent, including a subcontractor, to whom it provides such information agrees to implement reasonable and appropriate safeguards to protect it; (C) Report to the covered entity any security incident of which it becomes aware (D) Authorize termination of the contract by the covered entity, if the covered entity determines that the business associate has violated a material term of the contract. (ii) Other arrangements. (REQUIRED) (A) When a covered entity and its business associate are both governmental entities, the covered entity is in compliance with paragraph (a)(1) of this section, if – (1) It enters into a memorandum of understanding with the business associate that contains terms that accomplish the objectives of paragraph (a)(2)(i) of this section; or (2) Other law (including regulations adopted by the covered entity or its business associate) contains requirements applicable to the business associate that accomplish the objectives of paragraph (a)(2)(i) of this section. (B) If a business associate is required by law to perform a function or activity on behalf of a covered entity or to provide a service described in the definition of business associate as specified in §160.103 of this subchapter to a covered entity, the covered entity may permit the business associate to create, receive, maintain, or transmit electronic protected health information on its behalf to the extent necessary to comply with the legal mandate without meeting the requirements of paragraph (a)(2)(i) of this section, provided that the covered entity attempts in good faith to obtain satisfactory assurances as required by (a)(2)(ii)(A) of this section, and documents the attempt and the reasons that these assurances cannot be obtained. (C) The covered entity may omit from its other arrangements authorization of the termination of the contract by the covered entity, as required by paragraph (a)(2)(i)(D) of this section if such authorization is inconsistent with the statutory obligations of the covered entity or its business associate.
164.314(b)	(1) Requirements for group health plans. Except when the only electronic protected health information disclosed to a plan sponsor is disclosed pursuant to §164.504(f)(1)(ii) or (iii), or as authorized under §164.508, a group health plan must ensure that its plan documents provide that the plan sponsor will reasonably and appropriately safeguard electronic protected health information created, received, maintained, or transmitted to or by the plan sponsor on behalf of the group health plan....	(2) (REQUIRED) The plan documents of the group health plan must be amended to incorporate provisions to require the plan sponsor to– (i) Implement administrative, physical, and technical safeguards that reasonably and appropriately protect the confidentiality, integrity, and availability of the electronic protected health information that it creates, receives, maintains, or transmits on behalf of the group health plan; (ii) Ensure that the adequate separation required by §164.504(f)(2)(iii) is supported by reasonable and appropriate security measures; (iii) Ensure that any agent, including a subcontractor, to whom it provides this information agrees to implement reasonable and appropriate security measures to protect the information; and (iv) Report to the group health plan any security incident of which it becomes aware.
<i>Policies and Procedures and Documentation Requirements</i>		
<i>Sections</i>	<i>Standards</i>	<i>Implementation Specifications</i>
164.316(a)	Policies and procedures. Implement reasonable and appropriate policies and procedures to comply with the standards, implementation specifications, or other requirements of this subpart, taking into account those factors specified in §164.306(b)(2)(i), (ii), (iii), and (iv). This standard is not to be construed to permit or excuse an action that violates any other standard, implementation specification, or other requirements of this subpart. A covered entity may change its policies and procedures at any time, provided that the changes are documented and are implemented in accordance with this subpart.	(REQUIRED)

Table 104-1 HIPAA Final Security Rule—Standards and Implementation Specifications Matrix—Cont'd

<i>Policies and Procedures and Documentation Requirements</i>		
<i>Sections</i>	<i>Standards</i>	<i>Implementation Specifications</i>
164.316(b)	(1) Documentation. (ii) If an action, activity or assessment is required by this subpart to be documented, maintain a written (which may be electronic) record of the action, activity, or assessment...	(i) Maintain the policies and procedures implemented to comply with this subpart in written (which may be electronic) form; and (i) Time limit (REQUIRED). Retain the documentation required by paragraph (b)(1) of this section for 6 years from the date of its creation or the date when it last was in effect, whichever is later. (ii) Availability (REQUIRED). Make documentation available to those persons responsible for implementing the procedures to which the documentation pertains. (iii) Updates (Required). Review documentation periodically, and update as needed, in response to environmental or operational changes affecting the security of the electronic protected health information.

REQUIRED VS ADDRESSABLE

The entity must decide whether a given ADDRESSABLE implementation specification is a reasonable and appropriate security measure to apply within its particular security framework. This decision will depend on a variety of factors, such as, among others, the entity's risk analysis, risk mitigation strategy, what security measures are already in place, and the cost of implementation. Based upon this decision the following applies:

- (a) If a given ADDRESSABLE implementation specification is determined to be reasonable and appropriate, the covered entity must implement it.
- (b) If a given ADDRESSABLE implementation specification is determined to be an inappropriate and/or unreasonable security measure for the covered entity, but the standard cannot be met without implementation of an additional security safeguard, the covered entity may implement an alternate measure that accomplishes the same end as the addressable implementation specification. An entity that meets a given standard through alternative measures must document the decision not to implement the addressable implementation specification, the rationale behind that decision, and the alternative safeguard implemented to meet the standard. A covered health care provider must comply with the applicable requirements of this subpart (e.g., Part 164 Security and Privacy, Subpart C – Security Standards for the Protection of Electronic Protected Information) no later than April 20, 2005

*Health Insurance Reform: Security Standards; Final Rule (68 FR 8334-8381 ~ Feb 20, 2003)

Part 164: Security and Privacy; Subpart C: Security Standards for the Protection of Electronic Protected Health Information

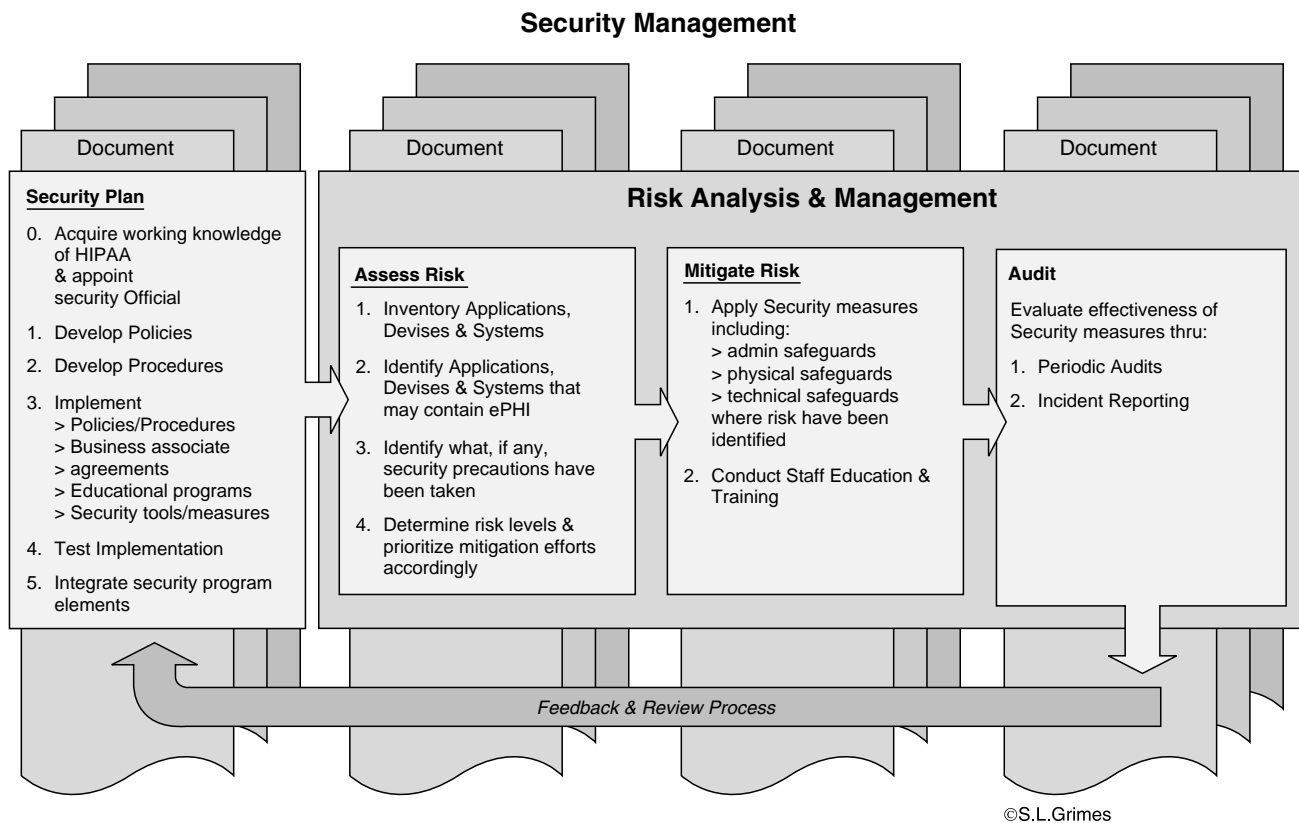

Figure 104-4 Security management and risk analysis and management process under HIPAA.

size, complexity, and capability) of the organization. These policies must address such issues as:

- Security management
- Sanctions
- Workforce security
- Information access management
- Security incidents
- Contingency planning
- Business associate agreements
- Periodic evaluations
- Facility access controls

- Device/system use (i.e., systems maintaining/transmitting ePHI)
- Device and media controls (i.e., devices and media maintaining/transmitting ePHI)
- Integrity (i.e., protecting ePHI from alteration or destruction)
- Documentation maintained for 6 years, reviewed and updated periodically

Level 2 Develop and adopt the necessary procedures, including physical and technical safeguards, per the security rule's implementation specifications. After developing the policies that address the security rule's standards and that are appropriate for the organization, the provider must then develop complementary procedures, physical and technical safeguards that track the security rule's implementation specifications. Examples include the following:

- Risk analysis, risk management, and system activity review procedures to address the security-management policies
- Authorization/supervision, workforce clearance, and termination procedures to address the workforce security policies
- Access authorization, access establishment/modification procedures to address the access management policies
- Security reminders, log-in monitoring, and password management procedures to address security-awareness policies
- Security response and reporting procedures to address security incident policies
- Data backup, disaster recovery, emergency-mode operation, and testing procedures to address contingency plan policies
- Business associate procedures to address business associate policies
- Evaluation procedures to address evaluation policies
- Contingency operations, facility security plans, access control/validation, record maintenance, and physical safeguards to address facility-access policies
- Device/system use and security procedures and physical safeguards to address system-use and security policies
- Data disposal, media re-use, system/data tracking and data backup/storage procedures and physical safeguards to address device- and media-control policies
- User identification, emergency access, automatic logoff, and encryption/decryption procedures to address access control policies
- Audit control procedures and technical safeguards to address audit-control policies
- Data verification procedures and technical safeguards to address data integrity policies
- Integrity control and encryption procedures and technical safeguards to address transmission security policies
- Documentation procedures to address documentation policies

Level 3 Implement policies/procedures, business associate agreements, workforce education, and physical/technical safeguards

After developing an appropriate complement of policies, procedures, physical and technical safeguards to meet the security rules requirements, the provider must effectively implement these measures.

Level 4 Test implementation

After implementing policies, procedures, and physical and technical safeguards, the provider must conduct on-going testing to verify their effectiveness and to determine which changes are required to keep the measures effective.

Level 5 Integrate security measures into an organization-wide program

Finally, the provider must ensure that these measures are integrated into their overall operations and security programs. Only after achieving integration can the security management program be considered effective.

Risk Analysis and Management

Simultaneously with establishing a security plan, the security rule requires that the provider incorporate risk analysis and management elements into the process. For biomedical technology programs, these elements involve the following:

An Inventory

The provider must identify biomedical devices and systems that maintain and/or transmit ePHI. Typically, for each affected device/system the organization should answer the following questions:

- What type(s) of ePHI does the device/system contain?
- Who has access to the ePHI? Who needs access?
- What types of connections with other devices/systems exist?
- What types of security measures are currently employed with this device/system?

Assessing the Risk Associated with ePHI in Inventoried Items

The provider should categorize the levels of risk with respect to the potential for compromises to confidentiality, integrity and availability of ePHI. The level of risk is determined by looking at both the degree of criticality (should ePHI become compromised) and the probability of such a compromise occurring.

- **Criticality:** Level of risk/vulnerability (e.g., high, medium, low) with respect to confidentiality, integrity, and availability of ePHI for each affected device/system
- **Probability:** Likelihood of risk (e.g., frequent, occasional, or rare) with respect to confidentiality, integrity, and availability of ePHI for each affected device/system
- **Composite risk score:** Combining criticality and probability levels into a composite risk score for each device and system maintaining or transmitting ePHI

Establishing Priorities

The provider can use the scores to assign priorities after establishing a composite risk score for each device and system maintaining or transmitting ePHI. The provider would:

- Use criticality/probability composite scores to prioritize risk mitigation efforts
- Conduct a mitigation effort that gives priority to devices and systems with highest scores (i.e., devices/systems that represent the most significant risks)
- Determining gap

According to priorities determined for each device and system in the inventory:

- Review existing security measures identified during biomedical device and system inventory process
- Prepare gap analyses for devices and systems detailing additional security measures necessary to mitigate recognized risks (addressing devices and systems according to priority)

Formulating and Implementing a Mitigation Plan

After determining the gap between existing and needed security measures and prioritizing devices and systems based on their risk levels:

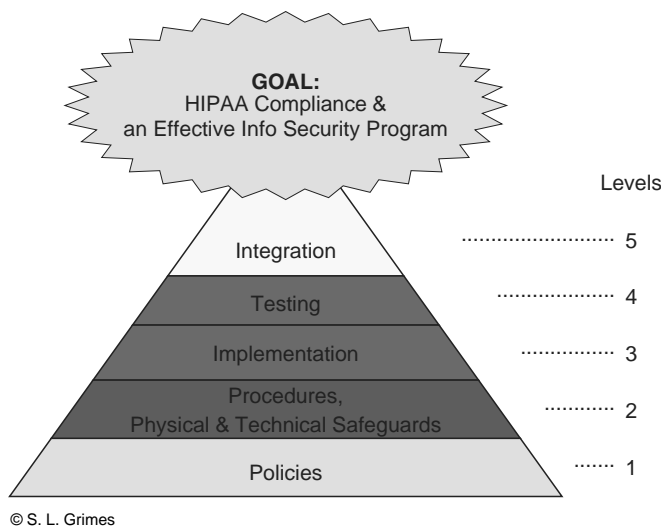

- Prepare a written plan incorporating
- Additional security measures as required
- Priority assessment
- Schedule for implementation
- Implement the plan and document the process
- Monitoring process

Ensure that the risk analysis and management process is continuously reviewed and improved as necessary by:

- Establishing on-going monitoring systems (including a security incident reporting system) to ensure mitigation efforts are effective
- Documenting results of regular audits of security processes

Summary

While the compliance process associated with HIPAA's security rule might seem onerous at first, consider that HIPAA has not so much placed an additional compliance burden on clinical engineers as it has legislated key elements of an effective clinical engineering or biomedical technology management program. Remember that HIPAA's administrative

Figure 104-6 Levels of risk with respect to confidentiality, integrity, and availability of ePHI for an affected medical device or system.

simplification provisions are, first and foremost, about standards. The standards in this case are facilitating the rapid and accurate exchange of patient-related information among providers, insurers, and others involved in health care operations. HIPAA's security rule requires that providers insure the integrity, availability, and confidentiality of patient-related information, including diagnostic and therapeutic data. Consider that ensuring integrity and availability of data in diagnostic and therapeutic devices and systems is an intrinsic and principle objective of any effective clinical engineering program. The security rule gives that objective the force of law and adds confidentiality considerations.

HIPAA is a major force in the future development of the U.S. health care system, and as such it will be an area of focus for most health care administrators and planners for many years. Clinical engineers should recognize their opportunity to contribute to ways to address this issue.

105

*For want of a nail, a shoe was lost.
For want of a shoe, a horse was lost.
For want of a horse, a rider was lost.
For want of a rider, a message was lost.
For want of a message, a battle was lost.
For want of a battle, a kingdom was lost.
And all for want of a nail. —George Herbert*

The British poet George Herbert used this verse to illustrate how a problem that at first might seem small (i.e., the lack of a nail) can sometimes have devastating consequences (i.e., the loss of a kingdom).

The Year 2000, or Y2K, technology issue had a simple genesis. Since the widespread use of computers in government, research, and business in the 1950s, computer programmers had used two digits in their software applications, rather than four, to represent the year. For example, the years 1952, 1977, and 1980 were stored and represented as "52," "77," and "80," respectively. At the time, this shortcut seemed to make sense. It saved keystrokes in data entry (e.g., it requires two fewer keystrokes to enter 01/01/52 than 01/01/1952), and required less computer memory and data storage capability, both of which were precious resources in early computer systems. When doing computations, it was safe to assume that only the last two digits of the year were significant (e.g., subtracting 52 from 80 yields the same result as subtracting 1952 from 1980). Whether calculating ages or interest rates, projecting dates, or scheduling routine activities such as planned maintenance, the use of two digits to represent the year was generally adequate.

Early programmers adopted the two-digit year convention, and subsequent generations of programmers and operators continued to use it without giving it further thought. Computers and their application programs proliferated throughout the latter half of the 20th century. They became faster, with higher capacities, while becoming smaller and more affordable. By the end of the 20th century, virtually every business in every industry was computerized. For most businesses, some computers and software applications had critical roles, i.e., the ability of the business to function depended on the ongoing, successful operation of the computer application. As businesses' needs changed over the years, they added staff programmers to modify existing software. As a consequence, core applications lasted beyond their projected life cycles, with supplements, modifications, and fixes added to meet business needs. Nearly all programs used the same two-digit year convention.

In the early 1980s, inexpensive personal computers appeared in the business environment and on the desks of key staff members, from the chief executive officer to the store-room clerk. These personal computers had internal clocks and often ran spreadsheet or database software that had been customized using for the most part the two-digit year convention. Computers also began morphing into other forms, appearing in such diverse environments as automotive subsystems, household appliances, industry tools, and medical equipment. These hybrid (often referred to as "embedded") systems often were

Y2K and Clinical Engineering

Stephen L. Grimes

Senior Consultant and Analyst, GENTECH
Saratoga Springs, NY

programmed with software on a silicon chip that kept track of time or dates using the two-digit convention.

The opportunities for the applications of computer technology seemed limitless. However, during the mid 1990s, reports of an inherent and perhaps fatal flaw in a broad spectrum of these systems began to surface. Some computer experts began speculating that many systems would produce unpredictable results and some might catastrophically fail as the world passed from the year 1999 to the year 2000. These failures would occur because many systems were not capable of recognizing that the year 2000 came after the year 1999. For example, when asked to determine the difference between the years 2000 and 1999, systems might calculate the difference between "00" from "99" yielding an erroneous result of "-99" (rather than the correct answer of "1"). The Y2K bug made its debut.

It Gets Complicated . . . "a kingdom was lost"

In the United States alone, it was estimated that 1.57 billion "function points" of software, roughly equivalent to 157 billion program lines of COBOL (COmmon Business Oriented Language—a popular business programming language of the 1960s and 1970s) existed by 1997 (Jones, 1997). This number did not include the millions of macro programs written by users for their spreadsheets or database applications. Affected software applications permeated all industries, including government, military, utilities, financial, manufacturing, and health care.

In the mid 1990s, as many industries began to assess their vulnerability to the Y2K bug, they realized the enormous breadth and depth of the potential impact. First, since adoption of the two-digit year convention by programmers had been nearly universal, virtually any function controlled by computer or containing an embedded computer might be affected. Problems could occur in missile defense systems, air traffic control, streetlights, telephones, water and electric power, and an endless list of other functions in other industries. Second, it was impossible to know which applications would be affected without testing. Applications were generally inadequately documented to identify which programs had the Y2K bug and where it existed within the program. Third, the problem was worldwide. Nearly every person on earth depended on services or businesses that were susceptible to the Y2K bug in some way. Most services and businesses were so interdependent that if some failed because they could in turn cause the failure of other business and services.

While many businesses and the public were unaware or unconcerned about Y2K in 1995, perspectives had changed by the end of 1998 and beginning of 1999. Governments and industries worldwide began to focus on solving the Y2K problem. A new industry of Y2K consultants and remediation services was spawned. As governments and industries assessed the scope of the Y2K problem, the following became clear:

1. The number of potentially affected computers and computer-based systems was so vast as to make comprehensive Y2K repair impossible. There were too few resources and too little time to effectively address the problem.
2. There was a wide disparity among governments, industries and the public in the perception of the seriousness of the Y2K problem and of the level of effort these groups were willing or able to spend on Y2K remediation.

In the United States, the executive branch of government took the problem seriously. Congress established special Y2K committees to oversee government and industry efforts to address the problem. Many state and local governments mirrored these activities. The United States Securities and Exchange Commission (SEC) required that publicly traded companies report their Y2K readiness status. Industry trade groups established guidelines for and provided educational services on Y2K remediation. Insurance companies amended their policies to limit their liability in not only in case of "acts of war" or "acts of God" but "acts of the Y2K bug." It is estimated that the United States spent between one and two trillion dollars to prepare for Y2K problems, of which \$13 billion was spent by the federal government (Luening et al, 1999).

By the late 1990s, a significant number of supposed experts were claiming all efforts were "too little too late" and worldwide disruptions in key businesses and services were imminent (Bergeon et al, 1999; Yourdon and Yourdon, 1998; Yardeni, 1998). The general public was advised to prepare for the worst and hope for the best. Common recommendations included taking a sizeable amount of cash from the bank to keep on hand, stocking food and water for days or weeks, keeping extra clothing and bedding available, filling automobile gas tanks, purchasing batteries and battery-operated radios and lanterns, and obtaining extra supplies of any needed prescription medications. By the end of 1999, the manufacturers of gas-powered electric generators could not keep up with the demands from concerned homeowners.

Much of the concern over the Y2K problem occurred because the problem was unprecedented and of such a wide scope that it was impossible to accurately predict the consequences. There was some question whether a simple convention adopted by a few programmers few decades earlier might topple (or at least incapacitate) businesses, governments, and basic society functions.

Y2K's Effect on Health care

The health care industry was late in responding to the Y2K issue. Like most other industries, health care employed computers and computer-based systems extensively in its operations and would face interruptions of those operations if the Y2K bug caused applications to fail. Potential failures differed in severity as follows:

- Catastrophic failures, including systems that completely shut down and fail to function
- Operational failures, including critical calculation and other processing errors (e.g., miscalculations causing errors in diagnostic results and in medication and other therapy delivery systems)
- Non-critical failures, including systems that provide erroneous date information but whose operations are otherwise unaffected

Catastrophic and operational failures of some applications, particularly those affecting patient diagnosis or treatment, could seriously impact on a patient's health and safety. Health care vulnerabilities fell into the following categories:

- Public infrastructure: Power, water, police and fire protection, public transportation, telecommunications are subject to their own "Y2K" failures and interruptions.
- Business dependencies: Third parties on whom the provider relies may experience "Y2K" related-failures that would compromise the hospital's ability to conduct its operations (e.g., drug and food suppliers).
- Computer systems: Medical information management systems, medical record and billing systems, networks, personal computers, and computer-controlled devices.
- Embedded processors: Non-programmable microcircuits "hard wired" into other pieces of equipment that may be critical to patient services or hospital operations, many of which include date calculations in their programming logic.

The embedded processor devices were considered a special risk for three reasons. First, embedded processor devices far outnumbered traditional computing systems. Nearly \$10 billion worth of microprocessors were manufactured and sold between 1991 and 1998, and of that number, only 10% were installed in traditional computers (Figure 105-1). The remaining 90% went into embedded processor devices. Second, since the processor and its application software were embedded, it was not obvious which devices had processors and might be affected by the Y2K bug. Finally, embedded processor devices that did have the Y2K bug could not simply be reprogrammed as traditional computers could. A device had to have its hardware changed or it had to be replaced. Typical embedded processor devices include the following:

- Medical devices and equipment, including infusion pumps, defibrillators, monitors, MRIs, CT scanners, dialysis machines, chemotherapy and radiation therapy machines, laboratory equipment, and other diagnostic and therapeutic systems
- Monitoring and control systems, including environmental and safety equipment
- Fire alarms, including detection and suppression units;
- Security systems, including badge readers and video and surveillance systems
- Telecommunications equipment, including telephones, call management and voice mail systems, pagers, cellular phones, and fax machines
- Building infrastructure, including HVAC, energy management and lighting controls, emergency generators and emergency lighting, backup power systems, elevators, and parking systems

Figure 105-1 Only 10% of processors manufactured between 1991 and 2000 were installed in computers. The remaining 90% were embedded in non-computers.

The interdependency of medical devices and systems added to the complexity of the Y2K problem. The weakest link would be the simple device in the chain that was not Y2K compliant and failure of that weak link threatened the entire system (see Figure 105-2).

The consequences of Y2K failures to health care providers fell into the three basic categories, illustrated by the following three figures:

Remedying Y2K in Medical Devices

The process of remedying Y2K in medical devices was daunting. Hospitals are enormous health care providers and own many medical devices. An average hospital might have 1000 to 5000 medical devices representing 500 to 1000 different device models and hundreds of manufacturers. Information technology (IT) staff's coordinated Y2K compliance efforts in most hospitals because they were responsible for the business computers and applications. However, IT professionals were often unfamiliar with medical technology and relied on the clinical engineering staff for assistance. Most clinical engineers broke the Y2K remediation process into five basic steps.

1. Limit further increases in risk exposure: All future medical device acquisitions had to be reviewed to ensure Y2K compliance. Y2K compliance terms were usually included on all purchase orders and manufacturers and required vendor certification.
2. Identify scope of existing Y2K risk: An inventory of all medical devices was created. That inventory was reviewed and a determination made as to whether devices were known to be compliant, non-compliant, or compliant status unknown. The United States Food and Drug Administration (FDA) had previously required all medical equipment manufacturers who sold their products in the U.S. to supply the compliance status of all their models. This FDA database was a major source of information about medical devices, followed by manufacturer web sites. In addition to compliance status, the inventory usually included an assessment of the critical nature of the medical device.

Typical critical assessment categories included the following:

- High risk and critical devices/systems are life support, resuscitation, or critical monitoring systems, or other devices that would seriously harm a patient if they fail.
- Moderate risk devices and systems would have significant impact on patient care if they failed, but failure does not pose immediate harm.
- Low risk devices and systems would have no serious impact on patient safety if they failed.
- No risk devices and systems, especially those not battery- or AC-powered, are unaffected by date changes and would have no impact on patient safety if they failed.

The inventory might include any known corrective measures (e.g., repairs, upgrades, or replacements that were necessary to secure compliance for non-compliant devices).

3. Develop/implement plan to address problem and insure compliance:

Following completion of the inventory, hospitals would prepare a plan to addressing all non-compliant devices and those with an unknown status. Priority was given to the most critical devices. If a device had an externally accessible clock/calendar and its Y2K compliance status could not be reliably assessed, it was tested. The testing typically involved verifying the devices ability to accomplish the following:

- a. Accept a new date
- b. Rollover between critical dates in both powered-up and powered-down states
- c. Re-initialize on power-up after critical date change

Non-compliant devices were brought into compliance through upgrades, modifications, repairs, or replacement (Figure 105-2).

Contingency plans were made to back up critical systems, and support staff members were on hand on December 31, 1999, to ensure that all critical systems made a smooth transition into the new millennium.

4. Monitor implementation of plan through 2000:

The remediation plan required regular reviews into 2000 to ensure that it remained effective and reflected updated information. Devices would need testing to verify that they remained compliant after undergoing modifications, upgrades, or repairs. Procedures to bring devices and systems into compliance were rechecked to reflect current information.

5. Status reports:

Regular progress reports to organization's Y2K coordinator were made regarding the status of medical device compliance. These reports typically included the following:

- a) Initial Y2K exposure and any subsequent changes in status
- b) Corrective actions taken and additional actions pending
- c) Preventive measures taken to limit additional exposure

The Outcome: Lessons Learned and Benefits Gained

As the clock ticked past 11:59 pm on December 31, 1999, and into the year 2000, all the fears of worldwide catastrophe were allayed. There were minor problems but nothing serious.

Was the Y2K problem over exaggerated? Perhaps it was. However, updates and upgrades on critical applications and systems did prevent some glitches from occurring. In addition, Y2K remediation provided many lessons and indirect benefits including the following:

- A better understanding of our reliance on technology and its vulnerability and perhaps a better appreciation of how small decisions can have unintended and significant consequences when constructing technical support systems.
- Contingency planning that incorporates means of addressing those vulnerabilities when elements of technology fail.
- An examination of existing technical systems and the overdue replacement of many that were obsolete or unsupported.
- The development of more effective risk assessment and management methods to avoid problems and prioritize remediation efforts.

The American Hospital Association (AHA) estimated that hospitals spent approximately \$8.5 billion in their efforts to remediate Y2K (Marietti, 1999). As a result, many hospi-

Figure 105-2 Testing, upgrading, modifying, repairing, or replacing devices and systems to bring them into compliance.

tals have updated medical technologies and are more knowledgeable with respect to the risks associated with those technologies. For clinical engineers, their Y2K remediation efforts provided an opportunity to gain insight and to learn valuable lessons on what is required to effectively manage evolving medical technologies.

The Integration and Convergence of Medical and Information Technologies

Ted Cohen

Manager, Clinical Engineering Department
Sacramento Medical Center, University of California
Sacramento, CA

Colleen Ward

Clinical Engineering Department,
Sacramento Medical Center, University of California
Sacramento, CA

Since the development of minicomputers in the early 1970s and the invention and implementation of the microprocessor in the late 1970s and early 1980s, medical products have become increasingly more dependent on computer technology. In fact, some clinical technologies (e.g., computerized tomography [CT] scanners) are entirely dependent on computers and could not function without them. More recently, microprocessors have become ubiquitous in medical technology and have been used in products including “smart” electric beds that weigh the patient and sense whether he or she is in or out of the bed; sophisticated implants such as implanted cardiac defibrillators; a large variety of medical systems that measure physiological parameters (*in vivo* and *in vitro*); and systems that image almost any portion of the anatomy. Today, many medical systems not only contain embedded microprocessors but also are capable of storing and communicating the clinical information they collect, over standard computer networks.

Information technology in health care has evolved from mainframe-based insurance and medical billing applications to a large variety of information systems, including laboratory, pharmacy, surgical, medical records, physician order entry, radiology, and picture archiving and communication systems. All of these information systems use acronyms that make them a little easier to remember (e.g., CPOE for Computerized Physician Order Entry, PACS for Picture Archiving and Communication Systems, and LIS for Laboratory Information Systems). Information technology in health care has adopted IT-standards-based data communication technologies (e.g., Ethernet, ATM, and category 5 cabling) that have allowed the relatively easy implementation of a standard data communications infrastructure throughout the modern health care facility.

Integration and Convergence

As clinical and information technologies have converged, two trends have emerged: (1) the widespread use of commercial off-the-shelf (COTS) hardware and software and (2) communication technologies that have interconnected the office, the enterprise, the community and the world (e.g., Transmission Control Protocol/Internet Protocol (TCP/IP), Internet). COTS technology significantly reduces manufacturers’ costs and improves manufacturers’ time-to-market for new products. These technologies allow many of the major medical systems that are sold today to operate as a computer system as well as a medical device. The modern hospital can interconnect these “medical devices” using standard data ports in patient care areas and standard wiring, hubs, switches and routers in data closets. These systems integrate information and clinical technology and support of these systems require an integrated approach by those who are trained and familiar with both the clinical and computer technology.

Combined together, the convergence and integration features result in systems like those shown in Figure 106-1. Such systems, with modified personal computers (PCs) as medical devices, are currently in use in a wide variety of inpatient (e.g., emergency room (ER), intensive care unit (ICU), acute care, operating room (OR), and outpatient settings (primary and specialty clinics) and include many different diagnostic and therapeutic devices and systems (e.g., lab, EEG, ECG, other vital signs, infusion pumps, and medical imaging).

With the use of standard PCs as the development platform, modern medical system design is now focused on system development with most of the effort going into software development and interfaces and, depending on the application, some additional development work being done on transducers (e.g., *in vivo* measurements of clinical laboratory parameters (e.g., blood gases, potassium, and sodium). For some systems, little hardware

work, other than an occasional interface circuit, is required. For other devices (e.g., respiratory therapy ventilators and anesthesia machines), microcomputers are included within the medical product, but considerable additional hardware design is still required. This critical equipment also has additional design challenges in order to meet critical life support requirements such as assuring that internal processor and system reboot times are very short.

The use of COTS and modern data communication technologies allows many of these integrated medical and information systems to provide new and robust features including automatic data collection, transmission, analysis and reporting, dynamic reconfiguration for differing applications without buying new hardware (e.g., pediatric vs. adult physiological monitoring, and remote software-version upgrading).

Another trend is the use of computers, both general purpose and specialty, to access multiple information systems. With the large number of computer information systems in a health care facility, a PC or terminal cannot be separately deployed for each clinical location for each information system due to cost and infrastructure (e.g., data closet, wiring, requirements and lack of space). Therefore, multiple applications are integrated on one system in order to allow almost simultaneous access to multiple information systems.

Figure 106-2 graphically depicts a computerized fetal monitoring system that has been adapted to allow access to laboratory data and a hospital information system as well as continuing to collect and process real-time fetal monitor data. When medical devices are used for such multiple applications, they require integration testing either by the manufacturer or the end-user. End-user integration testing requires that the manufacturer provide the end-user with an integration test procedure or software suite. This procedure is then followed to test for the proper operation of the medical device while the “foreign” integrated medical applications are operating. For example, in the fetal-monitor application depicted in Figure 106-2, full compliance with the integration test procedure assures that the real-time collection, processing and archiving of the fetal monitor data, including all its important features such as alarming for abnormal fetal heart rates, can be assured while the “foreign” applications are running. The more critical and time dependent the original applications are the more restrictive and conservative an integration test procedure must be. See Figure 106-3 for a portion of a sample integration test procedure.

Reliability and Quality Control

In order to ensure that medical systems based on COTS operate reliably, the entire system (i.e., transducer, interface, COTS hardware, COTS software, and application software) must operate together and reliably. COTS hardware can be extremely reliable. Typically, the weakest points from a reliability standpoint are COTS software (operating systems) and the application software.

Operating system software reliability is often expressed in terms of “nines,” with 99.0% up time equivalent to two nines. The reported reliability of Windows NT 4.0 is two

■ **Convergence:** ... *moving toward uniformity* ...

■ **Integration:** ... *process of incorporating as equals* ...

Figure 106-1 Definitions of convergence and integration.

OB Trace Vue with External System Access via Router

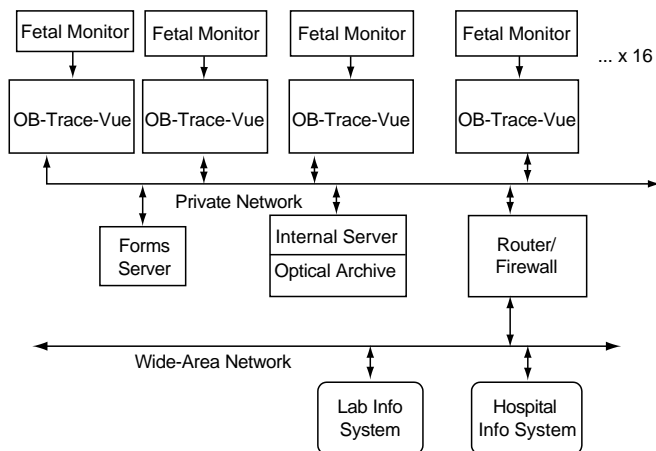

Figure 106-2 Fetal monitoring system with external access.

nines. For a continuously operating system, this equates to about 80 hours per year of down time. The reported reliability of Windows 2000 is 99.95%; i.e., three nines (five minutes per year of unscheduled downtime). Older versions of Windows were far less reliable. Further quantitative comparison of the reliability of various operating systems (e.g., UNIX vs. Windows 2000) is controversial and not yet well documented because there are no standards for software reliability measurement comparisons. Some companies have attempted to measure reboots per time period, but even that is suspect because different operating systems have differing scheduled needs for reboots, such as the reboot requirements that occur when new applications are installed in older versions of Windows. It is known and well documented that the newer versions of Windows (e.g., Windows 2000) are more reliable and require fewer reboots than the older versions (e.g., Windows 3.1, Windows 95, Windows 98). UNIX, and its many variants, is generally more reliable than the older versions of Windows. It remains to be seen whether the reliability of Windows 2000 can equal that of UNIX.

Integrated systems provide the medical device manufacturer with the challenge of ensuring quality at a level required for a medical device, while at the same time using COTS operating system software and COTS hardware that originally might not have been put through as rigorous a quality control protocol. In the United States, the FDA regulates medical device manufacturers and mandates that various quality control measures be in place. According to the FDA document entitled *Off-the Shelf Software Use in Medical Devices* (FDA, 1999), the medical device manufacturer who uses off-the-shelf software

“still bears the responsibility for the continued safe and effective performance of the medical device.” Like any medical device, the level of validation and verification required for software-based medical systems is based on the severity of the potential hazards to the patient, operators, and bystanders should there be a system failure, regardless of the failure cause, be it in hardware or software.

Software is very difficult to test exhaustively. Although it does not fatigue or catastrophically fail in the same way as a mechanical device or an electronic component, software problems occur regularly. These problems can range from applications that do not perform as designed and can restart with minimal problems, to operating a system stoppages that require reboots on a life support system, which could be catastrophic. Even when exhaustive testing has been performed, systems can experience software failures due to memory problems that develop over long periods of time (e.g., so-called memory leaks), user or operator error (e.g., inappropriate system recovery from erroneous keystroke sequences), lack of computer resources, and problems caused by foreign applications, viruses, or malicious intrusions. Medical device manufacturers must design systems to be as reliable as possible and so that failures are “soft” and do not harm the patient. As operating systems continue to evolve, their real-time functionality and reliability are also improving, and more critical applications and devices are using COTS-based systems.

Information System Security

A computer system or network can be considered secure only when its resources are available solely to authorized users and when use of those resources produces trusted results. A system that has been compromised by an intruder cannot be trusted. However, software bugs, user errors, or a malfunctioning sprinkler system are also threats to the security of a computer system. Clinical information system security is evolving. Security as related to patient data confidentiality in the United States is regulated by the Health Insurance Portability and Accountability Act (HIPAA) and is discussed elsewhere in this handbook (see Chapter 104). Designing security into medical information systems is an important feature and should include network-connectivity security issues, user name and password management, and update and version control, as well as physical security for the computer hardware, both servers and client workstations.

Computer security threats can be divided into errors of use and design and malicious attacks. Errors of use and design include authorized users making errors (e.g., accidental data deletion) and common software bugs (i.e., erroneous and/or incompletely tested software code). Malicious attacks include unauthorized users, authorized users maliciously viewing or altering data, authorized users knowingly or unknowingly giving away passwords, malicious code unknowingly placed on the computer (e.g., viruses, worms, trap doors or back doors, denial of service attacks, packet sniffing, or otherwise unauthorized electronic interception of data), and unauthorized physical access to data or systems.

Good system security design can preclude some of the malicious, as well as unintentional, security problems. For example, systems can force eight-digit passwords that include numbers, letters (upper and lower case), and special characters and therefore are far more difficult to crack than 3-digit numeric passwords.

OB TraceVue Archiving Functionality Test

Test Instructions Follow these instructions, marking your results on the Worksheet

Archiving Functionality
<p>Procedure 1: Partitioning the optical drive</p> <ol style="list-style-type: none"> 1. Connect the optical drive to the SCSI interface 2. Insert an optical disk into the drive 3. Start the server 4. Start Disk Administrator from the Administrative Tools menu 5. Format the optical disk 6. Create a partition on the optical disk
<p>Procedure 2: Checking the optical drive Archive</p> <ol style="list-style-type: none"> 1. With the third party running, start OB Trace Vue on the server with the optical drive and optical disk 2. Create one user and one bed using default basic alert settings 3. Assign Bed 1 to serial port A 4. Turn on the fetal monitor's recorder 5. Admit a new patient into Bed 1 6. Obtain a 5 minute trace with a fetal heart rate of 190 and toco that switches between 60 and 10. 7. Close the episode in Bed 1 8. Wait for 15 minutes 9. Retrieve the archived episode into Bed 1 10. Make a printout of the retrieved trace

Figure 106-3 Sample portion of an integration test procedure (Philips, 2001).

In addition, health care systems and system administrators help to protect against security problems by implementing all of the following:

1. The system administrator should develop a security guideline that documents all physical security, access controls, backup policies and procedures, audit policies, and other key security-related use parameters.
2. The system administrator should implement access control with data access privilege-level control (e.g., appropriate view, add, modify and delete privileges by individual user, and mandate unique user names and a strong password policy, including required periodic password changes. Where additional security is required, biometrics such as retinal scans, fingerprints, or handprints should be considered. Systems should have automatic logouts implemented, and users should not leave systems logged in and unattended.
3. Physical security must be managed. Access to data closets and server rooms should be controlled.
4. Backups should be performed routinely, and backup media should be stored in a separate location from their computer system, and preferably in a fireproof safe. Backups are probably the single most important security task!
5. System administrators need to implement software update and version control in compliance with the guidance of the medical system manufacturer. When manufacturers and regulatory agencies approve, operating systems and application programs should be periodically updated with available security patches and updates (e.g., virus detection and correction updates). It is the administrator's responsibility to keep up to date regarding announcements of security issues affecting the operating system and application software. When update announcements are made, the administrator must assess the impact on the system and take action in an appropriately timed manner, depending on the nature of the problem and the update status. Interim precautions or actions can be required until a permanent correction is developed, tested, and released by the manufacturer. The gap in time between when a security defect is discovered by hackers and the time that action is taken by the system administrator must be kept as short as possible to lessen the chance of further intrusion or new attacks. However, timing is particularly a problem for systems cleared by the Food and Drug Administration Center for Devices and Radiological Health (FDA CDRH), where version control and significant manufacturer testing are required prior to update implementation.
6. In some cases, for network protection, a firewall or virtual private network (VPN) can be installed to control access into and out of specific locations via domain, Internet Protocol (IP), and other network access control methodologies. Firewalls can be programmed to control all access into and out of a local or wide area network. A VPN can be implemented to encapsulate and encrypt private data over a public network so that it cannot be intercepted easily.
7. Where additional security is required, it can be provided by various encryption techniques. For wireless systems, the Wired Encryption Privacy (WEP) is one common encryption standard.
8. Where available, the logging and auditing of all administrator accesses, possible intrusion attempts (e.g., failed log-in attempts), and other significant events should be implemented.

In general, what should be done if a major security breach is discovered? First, refer to the security policy and then back up the entire system to disk in a disk space that is not currently in use (system snapshot). If the system is networked, disconnect it from the network if that is the likely source of the security breach or if the source of the breach is unknown. Further evaluate the security breach to determine what occurred and what was compromised. This will determine what additional actions must be taken, to first correct any compromised data or programs (e.g., restore using latest data backups and original program disks, where needed, patch the security breach so that it is less likely to occur in the future, and then determine whether additional action needs to be taken, such as notification of appropriate administrators or law enforcement agencies.

Vendor access to a medical information system for troubleshooting and upgrades is an increasingly more common feature, but it presents security challenges. Common vendor-access methods include dial-up modems, network (e.g., WAN) access, and access via a VPN. Where staff are present, modems provide a simple connectivity method and allow the end-users to disconnect the modem when it is not in use. However, when the information system is in a secure or remote location, or a location that is not staffed, then it is not practical to turn the modem on and off; modems become security risks. WAN access is simple, but it can be quite insecure unless access is controlled by a firewall or other authorization methods. Installing VPN equipment provides a much more secure method as it uses public infrastructure but provides IP control, similar to a firewall, and also encapsulates and encrypts the data. Of course, with all of these external access methods, user name and password management are also important. Leaving a persistent Internet connection (non-VPN) constantly open with a generic user name and no password is an invitation to an unwanted intrusion.

In summary, the greatest security challenges are caused by the manufacturer or the end-user not complying with good computer security design and implementation practices as discussed above. Poor practices that can lead to corrupted systems include users and system administrators allowing "generic" user names; no passwords or passwords that are easily broken; no physical security, resulting in systems being available to unauthorized individuals for unsanctioned activities; network connections to an intranet that are really connections to the public Internet with no firewalls or other intervening security measures; networked systems without virus-scanning software; and nonexistent or inadequate audit trails that prevent adequate security breach follow-up action to take place. Of course, periodic backups can ease the pain of recovering from any data loss, whether malicious or unintentional.

Support of Computerized Medical Systems

Computerized medical systems offer several support advantages for both the manufacturer and the end-user. Built-in system self-tests allow devices to test themselves and to determine whether they are working properly or not. Therefore, some networked devices can self-test

and, when they are not working properly, automatically "phone home" and tell their manufacturer that there is a problem. For software problems, remote access (automatic or manual) can then be used to fix the problem. Other advantages include online, fail-safe, "high-availability" systems that include a constantly running second computer that "mirrors" the operation of the primary system and takes over operation if a problem occurs.

Support Challenges

System integration provides a new set of challenges for the manufacturers and support staff for these complex systems. New methods must be developed to manage and support these systems. For example, the health care institutions and the manufacturers need to track and control software versions and upgrades more effectively, including manufacturer-provided COTS software and application programs. There is a conflict between the FDA requirements for version control and the ever-changing versions and service packs being added to COTS software. On network-connected information systems, and all their nodes, this conflict particularly impacts updates for security improvements for operating systems and virus-scanning software.

Other support challenges are further described in the following sections on hospital infrastructure, training and education, and documentation.

Infrastructure

IT standards-based medical systems allow communication via TCP/IP and other standards that hasten interconnectivity. Systems based on standards also allow common data infrastructure to be installed during construction and prior to knowing which specific clinical system will be purchased. Other advantages include installing computer hardware in the data closet and saving space in the clinical location. Challenges include building the data closets large enough to house more increasingly sensitive, equipment, color coding (or otherwise identifying) cables and other closet hardware, particularly for real-time medical systems, in order to separate them from office and other noncritical applications. Uninterruptible power supply (UPS) or emergency power must be provided to these systems in case of power failure and to ensure continuous operation during emergency generator tests. Access to the data closet must be controlled, but medical systems support staff must be allowed access.

Several wireless technologies have penetrated the health care market including 802.11b in clinical telemetry applications, micro-cellular internal-to-the-hospital cellular phone systems, and wireless personal digital assistants (PDAs) for medical staff. Both frequency management and access point (antenna) location management are required in order to avoid interference between all of the varieties of wireless technologies currently vying for the health care market. In order to reduce wireless infrastructure, standardization of the various wireless technologies is important, but it is currently difficult because of the large number of different wireless standards in use (e.g., IEEE 802.11a, IEEE 802.11b).

Training and Education

Information technology (IT), clinical engineering, and biomedical equipment technology professionals who support these converged medical and information systems have new training needs, with the IT staff needing more clinical knowledge and the biomedical/clinical engineering community requiring additional computer and IT training. Clinical engineer and BMET training must include fundamental computer technologies including operating systems e.g., Microsoft Windows, UNIX, databases, applications, communication technologies e.g., Ethernet, TCP/IP, Internet, Asynchronous Transfer Mode (ATM), and wireless, and new computer technologies e.g., storage area network (SAN), plus clinical information system education. Security, patient data confidentiality, and other public issues associated with data communication are issues that everyone must understand better.

Documentation

The clinical engineering literature contains many articles regarding required service documentation for medical instrumentation. However, little has been written about ways to document complex, computer-based medical instruments, particularly computerized information systems. One approach is to require the following: (1) as-built drawings; (2) operator manuals and specifications for each component; (3) service manuals and troubleshooting information for critical components; and (4) software tools to aid in troubleshooting.

As-built drawings provide a way to document the system after it is installed, showing all wiring, hubs, routers, servers, access points, and workstations. Computerized, as-built drawings based on Adobe Acrobat® and PDF files are one way to develop as-built drawings. These network drawings can include "hot" links to printer and other peripheral information and also include information regarding the equipment's physical location, model, data communication paths, TCP/IP addresses, modem phone numbers, and more.

Traditional user's manuals including setup and configuration information are required and typically supplied. Service manuals are difficult to obtain, but critical for all systems and components that are not "off-the-shelf" and therefore can be difficult and/or expensive to replace. Any software troubleshooting tools that the vendor will make available to the customer should also be obtained and appropriate documentation provided in order to operate these tools.

Conclusion

Information technology is changing rapidly, and medical technology, although more slowly changing than information technology, is evolving rapidly. In the near future, new and emerging medical technologies that are based on IT include new wireless

networks (e.g., Bluetooth personal area networks, surgical robotics with tactile sensors, “smart” artificial limbs, advanced speech recognition, voice over IP telephones, reasonably priced digital broadcast quality video, and swallowable video endoscopes). Standards-based information and medical technology integration will easily allow workstations to communicate with multiple systems without special integration testing and concern over critical performance problems. Data-transmission rates will continue to increase, with costs continuing to decrease (e.g., gigabit Ethernet and faster digital subscriber line (DSL)). Data and voice infrastructure will merge, and data outlets will become as ubiquitous as electrical power outlets. Data closets and data infrastructure will continue to grow in size and complexity as the rate of equipment that moves from clinical spaces into the data closets increases faster than the size reduction of the equipment.

The clinical laboratory will move in two directions. For critical patients, point-of-care testing and indwelling sensors will become more commonplace. For the main lab, increasingly more tests will be performed via automated, robotics-based laboratories. Nursing unit central stations will become increasingly less important as physiological monitor alarms, “nurse call” requests, and other critical information are communicated directly to the assigned care givers. The acuity level of the inpatient will continue to increase, and technology will be moved to the inpatient’s room, rather than the patient being moved to the technology.

Continuing education of all clinical and support staff is required in order to stay abreast of these changes. New paradigms in health care technology leadership are required for managing integrated clinical and information technology.

Section X

Engineering the Clinical Environment

Matthew F. Baretich

President, Baretich Engineering, Inc.
Fort Collins, CO

Clinical engineering is one among many engineering and technical professions that contributes to the design and operation of the clinical environment. At the most fundamental level, clinical engineers must coordinate their work with that of health care facilities engineers and environmental safety professionals. For this reason, clinical engineers should have at least a basic understanding of the principles and practices in these related areas.

However, there are good reasons to go beyond a basic level of knowledge. Clinical engineers often encounter opportunities to go from coordination to active cooperation, which means looking outside the typical definition of clinical engineering practice and finding ways to bring broader engineering principles to bear on health care facility design and operation. Only by fostering synergism among the various engineering and technical professionals within the health care delivery system can we maximize the contribution of engineering to patient care.

Clinical engineers are increasingly being asked to take responsibility for technical activities outside their usual areas of practice. Therefore, clinical engineers should develop an understanding of related professions so they can expand their roles within their organizations.

Beyond Clinical Engineering

The chapters in this section are not intended to make clinical engineers experts in the topics they address. They are, however, intended to provide an introduction to these topics and to point the reader towards additional sources of information. These chapters may be regarded as representative starting points for clinical engineers who wish to

expand their knowledge of related fields, and perhaps to expand their range of professional practice.

The first group of topics introduces the basic utility systems found in health care facilities. Hyndman provides an overview of the variety of systems that are behind the scenes supporting the patient care environment. In the next chapter, Hyndman presents a detailed description of heating, ventilation, and air conditioning (HVAC) systems and their roles in patient comfort, infection control, and indoor air quality. Baretich addresses electrical power systems, including both normal and emergency systems, as well as the isolated power systems used in some health care facilities. Frank provides a practical overview of medical gas systems, including storage and distribution systems for oxygen, medical-grade air, vacuum, and other gas systems used in health care delivery.

The second group of topics describes a range of activities in health care facility design and operation. Cram discusses the wide range of support service programs that are vital to the operation of health care facilities. Baretich addresses the role of clinical engineering in facility design, construction, and renovation.

The third group of topics covers a representative set of environmental safety issues. Strzelczyk presents an extensive overview of radiation safety, including specific examples of radiation safety programs. Brito and Magagna discuss hospital sanitation activities, including infection control, sterilization, and waste-handling. Hernández addresses water distribution systems and their roles in disease prevention and infection control. Epstein and Harding conclude with an overview of disaster planning in health care facilities.

The topics addressed in this section represent the nuts and bolts that we use to build an environment that supports high-quality patient care. In a very real sense, "engineering the clinical environment" is what we do.

Physical Plant

Bruce Hyndman

Director of Engineering Services, Community Hospital of the Monterey Peninsula
Monterey, CA

The physical plant (i.e., the “plant” of a building or complex) is generally considered to comprise the infrastructure elements that provide the utilities systems to the building. This chapter describes some of the common utilities that are considered to be elements of the plant. The utilities described do not constitute an all inclusive list of elements of the plant in a hospital, but they are representative of major systems.

Major physical plant elements are frequently housed in a central location for efficiency of construction and operation. Those elements thus installed and constructed are commonly called the “central plant.” A central plant may be housed in a separate but adjacent utility building or may exist inside the envelope of the hospital building. The central plant often houses hot water and steam boilers, chillers, and power generating equipment, or some subset of these elements. These large electromechanical devices have associated pumps, motors, pipes, conduits, wires, and flues. Other components of the plant are distributed and provide the pathways for distribution of the plant’s commodities and energy. To familiarize the clinical engineer with the plant, the plant elements are described in this chapter.

Life Safety

Fire Detection

Modern fire detection systems consist of one or more microprocessor-equipped cabinets with individual field devices attached to the cabinet by wiring and communications protocol. The devices may include the following:

- Smoke detectors
- Heat detectors
- Control units for fans and doors
- Visual annunciating devices (strobes)
- Audio annunciating devices (speakers, horns)

Modern fire alarm systems, also known as fire alarm control panels, are associated with a personal computer (PC) that loads the site-specific information, including the assignment of devices, the naming of devices, the annunciating protocols and messages, and the sequence of operations for control devices and annunciators. Options for these systems operations can include the amount of time a detector remains in alarm condition before a general alarm is announced, the length of time audible signals are active with a general alarm, and the form of the messages displayed for any condition. Large buildings and building complexes are equipped with multiple cabinets containing supporting devices. The cabinets within zones are linked to a common network. These systems may be smart enough to monitor and announce such conditions as dirty smoke detectors, missing devices, and open or ground fault conditions. Installation and maintenance of a fire alarm system is governed by codes and standards, usually adopted from National Fire Protection Association (NFPA) standards.

Fire Protection/Suppression

Sprinklers

The automatic sprinkler system is the primary fire protection system for hospitals. An automatic sprinkler system is a piped water system, usually fed from a street water main into the building through a set of pipes and valves separate from the domestic water system, although at the street level the water likely stems from the same main piping system. The sprinkler system has valves for each branch that are accessible to the fire department and can be locked in the open position. It also has electronic monitoring systems to indicate a closed or partially closed condition. The valves outside the building may be of the type known as a post-indicating valve (PIV), which has a window showing the words “open” or “closed.” Inside a building, the sprinkler system might have additional zone valves, but each valve is electronically monitored to create an alert condition if the valve

is closed or partially closed. The sprinkler system piping is distributed throughout the building to heat-activated sprinkler heads. At a specified temperature and after a specified time, each sprinkler head opens and sprays water over the area it serves. Water continues to flow until a control valve is closed.

Some systems operate strictly on water main pressure from the street. Others may have booster pumps to increase the sprinkler pressure to a desired level or to provide water from alternate source, such as storage tanks or a pond. A fire department connection may be part of the outside piping system, allowing a pumping truck to attach to the automatic sprinkler system and increase the pressure in the system or to add additional water if the main supply is deficient.

In addition to wet automatic sprinkler systems, dry standpipe systems may be installed on the exterior of the building to allow a water source such as a fire engine pumper to be connected, to provide water for fire hose connections or sprinklers within the building. Other fire suppression systems are used for selected areas in hospitals. Computer rooms may be equipped with Halon systems that use compressed fire suppression chemicals. These systems are operated electrically based upon a specific detection pattern in the room. If activated, a valve opens that results in the rapid release of the compressed agent into a closed room. Cooking areas with grills and other grease producing devices are equipped with exhaust hoods with heat-initiated dry chemical extinguishing systems. These systems release a fire-retarding chemical on the cooking area if the temperature in the exhaust hood reaches a specified temperature.

Other extinguishing systems, including compressed carbon dioxide systems, are in less common in hospitals. However, all systems are linked to the fire alarm system in the hospital so that activation of any single suppression system results in a general fire alarm. In the case of the sprinkler system, flow detection devices in the sprinkler pipes initiate a fire alarm. Other systems provide alarm signals to the main fire alarm system through relay contacts or other means.

Barriers

Fire protection in hospitals is provided in part by the elements of the buildings’ construction. Barriers to the spread of smoke and fire include walls, doors, and dampers.

Hospital construction requirements specify the materials and configurations to contain fire and smoke within rooms and compartments to allow time for the fire to be extinguished and to protect the paths of egress from the area or from the building.

Extinguishers

In addition to the automatic sprinklers and non-water suppression systems, hospitals have a large inventory of hand-held extinguishers of various sizes and specifications or ratings. These devices require regular inspection and testing.

Hoses

Some hospitals may have fire hoses that are attached to the automatic sprinkler piping so building occupants can suppress or extinguish a fire. Operation of these hoses results in a flow alarm from the fire alarm system.

Hydrants

Hospital properties have standard fire hydrants at specified intervals on the perimeter of the property for use by fire department trucks. The hydrants must be tested regularly for proper flow and static pressure.

Egress Signage and Lighting

The required “Exit” signs in hospital buildings are an important element of the life safety systems. The signs may be illuminated by LEDs or light bulbs, or may be self-illuminating with radioactive luminous material. Certain light fixtures along the path of egress from any building must be supported by an emergency power source to provide a lighted pathway during a fire or other emergency that interrupts normal power sources.

Emergency Electric Power

Specified electric loads in a hospital must be supported by a backup emergency electric supply. A common compliance method is the installation of diesel-fueled engine generator sets. These devices are connected through automatic transfer switches (ATS) that sense loss of normal power and automatically operate a mechanical switch to connect the required loads to the output of the engine generator set. In some cases, loads other than required loads may be connected. Gasoline, natural gas, or other fuels can power engine-generator sets. Steam or jet turbine-driven generators are also used to supply power to hospitals but are not commonly used as emergency backup generator systems. In one case, steam-driven generators were specified as normal power and the public utility system specified as the emergency backup. Code requirements generally include the ability of the engine generator set to start, come to full speed, operate the ATS, and connect to and support the required electrical loads within 10 seconds after failure of normal power sources. (See Chapter 109 for more information about emergency electrical power.)

Lighting

Lighting is a major energy user in a hospital and entails a variety of fixtures and incandescent and fluorescent lamps of various luminosities. Lighting controls may be sophisticated to improve energy efficiency, but generally lighting in hospitals remains at a constant level because of the nature of hospital operations.

Vertical Transport

Vertical transport may be accomplished by elevator, or by escalator in some cases. Elevators can operate independently or can have control systems that optimize the locations of elevators based upon some predetermined rules, such as time of day, floor priority, and user priority.

Normal Electric Power

A local utility company most often provides normal electric power to hospitals. Electric power can be purchased at a user voltage level of 208 or 480 volts, for example, and the transformed to other voltages for some hospital use. In this case, the utility company will own large transformers on or near the hospital property, because the utility company owns the electric power at the street at higher voltage levels, such as 21 kilovolts or 12 kilovolts. Hospitals may choose to purchase power at the higher voltage to obtain a discount, and then own a small, high-voltage electric system with their own transformers to reduce the voltage to a service level. Understanding utility rate structures is an important part of operating a hospital and minimizing utility bills. (See Chapter 109 for a further discussion of normal electrical power.)

Domestic Water

A local water company or utility sells water for bathing, drinking, cooking, and sanitary sewer systems. Much of the water used in a hospital on a daily basis may be for comfort control, and it evaporates into the atmosphere from cooling towers. A chilling system can use more than 10,000 gallons of water per day. Domestic water may require treatment before use in boilers and other equipment to reduce hardness or contaminants that damage to pipes or systems. (See Chapter 115 for further information on water.)

HVAC

Heating, ventilation, and air conditioning (HVAC) systems are comprised of the following major components:

- Heating hot water
- Chilling pumps, cooling towers, and chillers
- Water treatment
- Fans

- Controls
- Humidification

A full discussion of these elements appears in Chapter 108.

Sewers

Sanitary Sewer

Unlike home sewer systems, hospital sewer systems must accommodate caustic chemicals, grease from major kitchen operations, chemically treated water from boilers or cooling towers, silver-contaminated water from film development, and other effluents not found in household sewage. To accommodate the various effluents, sanitary sewer systems may include grease interceptors or traps, mixing or diluting systems, exotic pipe materials such as glass, and effluent treatment systems using enzymes or bacteria.

Storm Sewers

Storm sewers are different from the sanitary sewer systems. Storm sewers handle water runoff from rain, snow, or irrigation. Separation of sewer systems to comply with local codes may require special attention in some areas, including loading dock or trash compactor areas, where contaminants from washing or spills must be carefully separated from rainwater into different sewer systems. (See Chapter 114 for further information on sanitation.)

Medical Gases and Vacuum

Piped medical gas systems in hospitals include medical air and oxygen, as well as nitrous oxide and nitrogen in some areas. Piped medical vacuum systems are usually considered a part of these systems. Piped systems operation requires knowledge of pressure regulation, gas alarm systems, bulk liquefied gas storage systems, high-pressure gas storage cylinder handling, and manifold cylinder delivery systems. In addition, hospitals typically have a variety of non-piped gases supplied in cylinders, including carbon dioxide, carbon monoxide, and other gases used for testing in various applications. Careful maintenance and operation are required to preclude delivery of the wrong gas or any gas at the wrong pressure. Chapter 110 contains a further discussion of medical gas systems.

Steam and Natural Gas

Steam boilers in the central plant generally produce steam for use in heating, sterilization, cooking, and humidification and pipe it to the end user. Natural gas, fuel oil, propane, or other fuel may fire steam boilers. In some areas, steam can be provided as a commodity from a local utility and piped in from outside the hospital. Natural gas also can be used as a commodity to heat hot water, steam, domestic hot water, cooking, and other services.

Communications

Modern communications systems include a variety of hard-wired and wireless systems. The hospital might operate a telephone system that is provided as a service from a local telephone company, but it usually owns a telephone system termed a "Private Business Exchange (PBX)." PBX systems comprise a central "switch," i.e., the electronics that control the telephones, the calls coming in on wires or fiber from outside the hospital, and the local network inside the hospital. In addition, a hospital can operate a telephone system that is linked to the internal data network system using internet protocol devices. Other communications systems operated and maintained in a hospital can include nurse call systems, radiofrequency devices, such as two-way radios and repeaters, "beeper" systems, and cellular telephone systems for use inside or outside the hospital. Some hospitals use pneumatic tube systems in which carriers are moved through a system of tubes from location to location with vacuum or pressure. The pressure systems require a control system to sort and direct carriers to the correct destination and can have sophisticated routing computers to optimize their use.

Bruce Hyndman

Director of Engineering Services, Community Hospital of the Monterey Peninsula
Monterey, CA

“Heating, ventilation, and air conditioning” (HVAC), is an umbrella term that encompasses many individual generic types of equipment and systems, usually with subsystems and subcomponents. The components of HVAC systems in general include fans, dampers, coils, filters, humidifiers, and controls. The engineering study of the design and operation of such systems falls largely within the realm of mechanical engineering. It is not the intent in this chapter to provide the engineering theory, design parameters, or specific operating guidelines for such systems. Such information is provided in large volumes of handbooks and texts and is too broad in scope to address here. The purpose of this chapter is to provide a simple overview of these systems that will allow clinical engineers to be familiar with the systems and equipment and their functions.

HVAC systems are generally integrated, although they can be separate. For example, a radiant heating system that does not employ heated air supplies as the primary method of heating may be used. Even in that example, it is likely that the minimal heating of supply air will use the same source of heat as the radiant heating system. In the simplest model, the central system to the HVAC operations is the air handler, shown in Figure 108-1 with its various elements. A building requires ventilation for fresh air and to exhaust the products of human ventilation and processes. Simple systems take fresh air from outside the building, using a fan, and they blow the fresh air through ducts to every room in the building, where it enters the rooms through vents. Air is similarly exhausted by being drawn out of the rooms through vents into exhaust ducts that blow it out of the building and into the atmosphere.

Associated with the fans and ducts that move air in or out of the building are systems that filter the air, humidify or dehumidify the air, heat the air, cool the air, and control the volume of air supplied to the duct work and, in some cases, to each room. Remembering the basic air supply system, the individual additional systems and elements are described below.

Supply and Exhaust Air Flow and Pressure

Codes and standards usually dictate the required amount of air to be supplied and exhausted into any room or area of a hospital. These will vary according to the use of the space. The design parameter is expressed in “room air changes per hour.” Knowing the room volume allows the designer to specify a volume of air to be supplied (in cubic feet per minute (CFM)) for a room that might be divided among several duct outlets or vents in the room. The pressure relationship of each room, with respect to adjacent spaces, likewise probably will be dictated by codes or standards. Some medical circumstances require special ventilation. “Isolation” rooms might have a specific code definition and requirements. In general terms, there are needs to prevent air from entering a room or, in some cases, from leaving a room.

Patient rooms housing transplant patients with suppressed immune systems need to minimize the possibility of contamination from airborne pathogens that may be found in the hospital but at levels not harmful to a healthy individual. These rooms are typically maintained at positive pressure relative to the hallway and adjacent spaces and might include a two-door isolation system with an intervening space between the hall and the room. In this configuration, the room is positively pressurized with respect to the intervening space and the hallway so that air tends to flow out of the room, rather than into it through an open door. This pressure relationship is established by supplying more air to the room than is exhausted. Testing and monitoring such conditions can be accomplished by using differential pressure measuring systems with alarms or can be confirmed by using smoke to visualize the actual flow of air at the door when it is opened. More sophisticated testing can be performed using trace amounts of elements tagged to the ventilation air and can be monitored with specific detectors.

Rooms that house patients with infectious diseases (e.g., tuberculosis) will be designed to prevent airborne pathogens from leaving the room and entering the hospital’s general air circulation. Such rooms are kept at a negative pressure relationship to the hall and adjacent areas. This is accomplished by exhausting more air than is supplied, it and can include high-efficiency filtration of exhaust air to reduce the possibility of contaminating outside air in the vicinity of other air intakes.

An office space requires the minimum amount of air exchanges per hour and is neutral in pressure with respect to adjacent spaces. An operating room requires greater air-exchange rates and might have an unbalanced supply-to-exhaust relationship. Special cases for isolation rooms, clean rooms, and other applications sometimes exist. Systems can be as simple as a fan running at a fixed speed for supply and exhaust with ducts equipped with internal dampers that are adjusted to “fine tune” the volumes being delivered from each branch of the duct. More complicated systems might have variable air volume (VAV) schemes that use variable speed motors to drive fans or variable aperture vents at the end of the ductwork supplying each area. Another variation of controls incorporates a constant volume vent at the end of the supply duct to compensate for any changes in pressure elsewhere in the ventilation system. One could model a sophisticated air supply and exhaust system against the human cardiovascular system, with flows and pressures changing in individual branches of the system, requiring compensatory changes in flow and pressure elsewhere in the system.

In many designs, return air systems are included, rather than simple exhaust systems. A forced air furnace for a home probably has a single fan that draws air from the house and blows it through a heating chamber and then back into the house. Return-air systems for hospitals function in a similar way but use separate fans to remove air from the building and return it to the intake of the supply fan, where some part of the returned air is exhausted to the atmosphere, and the difference is made up of fresh outside air. Again, codes and standards will dictate the minimum percentage of outside air that must be supplied to the building. Return air systems are used to conserve energy for either cooling or heating. Imagine, for example, that the outside air temperature is 30°F. This air is heated as it travels through the air handler and is then supplied to rooms in the building, where it may be heated even more to achieve a desired room temperature. In a system that uses 100% outside air for supply, the energy cost of heating the air would be higher than that of a return air system that used 20% outside air and 80% return air since the returned air already would be at or near the target room air temperature and would not need to be heated. Using a variable percentage of outside air (versus returned air) through control of dampers is known as an “economizer cycle”. Economizer control routines might be simple and controlled at the air handler or might be part of a larger building automation and energy management system.

Exhaust systems for ordinary air handlers typically are not filtered, but exhaust systems for isolation rooms for tuberculosis patients, or for chemical or other fume hoods, might require specific filtering and special isolation from air intakes and staff or public exposure.

Filtration

All air supply to hospitals is filtered. Filtration, as other specifications, is dictated by codes and standards. General use areas have enough filtration to eliminate from the air particulate matter that could cause maintenance problems with components of the air supply system or general cleaning problems, and to eliminate the intake of animal life.

Air can be filtered at the intake and/or along the path to delivery to rooms in the building. An OR probably will be supplied with air that is filtered first at the outside air intake and then again as it enters the main duct in the air handler. The efficiency of the second stage of filtering will be higher than that of the first stage and thus will filter out smaller contaminants. For some rooms, final filtering at the duct entering the room might be required. These are special use rooms for clean room applications, for some types of surgical procedures, or to protect some kinds of patients who are extraordinarily susceptible to infection.

Filter testing and maintenance are typically based upon the measured differential pressure across the filter. With a known air flow rate, the resistance of the filter can be calculated based upon the area of the filter and the flow. Manufacturers of filters will specify a range of resistance or pressure differentials that constitute a normal range of operation. Higher resistances indicate occlusion of the filter, lower resistances, breaches in the filter, or leaks in or around the filter. Testing of “filter drop” using differential pressure gauges can be performed with handheld equipment, stationary monitoring meters, or remote

monitoring and alarm systems. Handling of some exhaust filters requires special precautions, including filters from isolation rooms and from chemical and biological exhaust hoods.

Heating and Cooling

Heating of room spaces in a hospital can be direct, with local radiant heating, but it is more likely done by heating the air supplied to the room. One method of supplying heated air to spaces in a hospital is the "terminal reheat" method or design in which air taken into an air handler is heated to a target temperature in the main duct in the air handler. This heating is accomplished by passing the air through a heat exchange coil (as in a car radiator) that contains hot water supplied from a hot water system. The temperature of the water in the coil is controlled by valves and is based upon reaching a desired target for supply air temperature. For example, if the air supply system is designed for a constant air supply temperature of 55°F, the valve controlling the supply of hot water to the heating coil will close as the supply air temperature approaches 55° and will open wider if the supply air temperature begins to drop below 55°F. In the terminal reheat system, the 55°F air (or some other target temperature air) is blown down the ductwork until it nears a room (or group of rooms) the temperature of which is controlled by a thermostat (i.e., a reheat zone). There, the air passes through a second, smaller heat exchanger controlled by the zone thermostat. If the thermostat is set for 72°F, and the room air is 70°F, the thermostat will operate a valve at the local heating coil to allow hot water to flow and to "reheat" the air to some higher temperature until the room air (mixed) rises to 72°F, at which point the thermostat will control the heating coil valve to stop the flow of hot water.

The process for precooling is the same in such a system at the air handler with a separate cooling coil at the air handler for this purpose. Because building spaces usually produce some heat from the equipment and occupants, no secondary cooling is required. In the above example, 55°F air is blown into the rooms at the end of the ductwork. The designer would have calculated the worst-case outside air and heat generating characteristics of the room and would have supplied a sufficient number of air exchanges so that, in the worst case, 55°F supply air would keep the room at a desired temperature. If, on a hot day, the room were not warm enough, the air would be "reheated" by the local thermostat and coil combination (hence, the name for this type of system design). More sophisticated methods of controlling room temperatures can control the overall supply air temperature based upon room temperatures, or can vary the flow of air into the room to control the exchange of heat from outside to inside.

Heating of the water that flows through hot water coils in the air handlers and at the individual heat zones can be accomplished with hot water boilers, steam heat exchangers, or other methods. Cooling or chilling of the air may be accomplished with chilled water or with direct heat exchange with refrigerant coils. A discussion of the physical plant in a hospital is addressed in Chapter 107.

Control Systems

The simplest notion of controlling an HVAC system is the control of room temperatures by controlling air temperatures, as in the case of adjusting a room thermostat to "turn up the heat" or "turn on the air conditioning". In the simple, forced air furnace system used in homes, a thermostat might or might not be equipped with a thermometer or temperature gauge but has some internal method of measuring temperature. The thermostat performs its function by completing an electrical circuit to turn on the furnace when the occupant moves the target or desired temperature indicator above the current temperature. The "sequence of operation" for such an event in a simple, gas heated, forced air furnace is as follows:

1. The gas supply valve to the furnace burner will open.
2. A timer will start.
3. An ignition system will start (unless there is a pilot light, in which case step 1 will include verification of a pilot flame).
4. Verification of ignition by temperature (or of timer limit reached, and gas valve closed).
5. Power will be supplied to the fan motor to supply warm air through ductwork.

This is a simple example of the most basic system of controls for a single function in the process of ventilating a building and providing comfort controls. Of course, a hospital, that has hundreds or thousands of zones or rooms to be controlled with heating, cooling, humidification, and other features requires a much more complicated control system.

The actual moving parts of a hospital HVAC system are usually mechanical and electromechanical. The most common methods of controlling the individual devices and the overall process are with pneumatic controls that use compressed air, or with electric or electronic signals that drive solenoid-operated devices or motors.

Pneumatic controls use differential pressures and flows to push flexible diaphragms connected to mechanical valves and similar devices to operate switches, open or close valves, or move dampers. An example of one element of such a system is shown schematically in Figure 108-1. In this example, an air heating device (a reheat coil) in the duct supplying air to a room is controlled by a pneumatic thermostat and a pneumatically actuated water valve.

Direct digital control (DDC) is a system of controls using software and firmware to control sequence of operation. In a DDC system, conditions in a system are measured as analog or digital inputs, and operating instructions to devices are created as digital output signals. In the case of controlling the same reheating device above, the room thermostat would provide a digital representation of the existing room air temperature, and the occu-

pany operated temperature selection device could be an analog signal converted to a digital value to be compared to the digital value of the current room temperature. The consequence of a difference in the two values is whatever the system programmer chooses, but in a normal case it could be a digital output signal that operates an electronic relay supplying power to a solenoid-operated hot water valve. A more sophisticated option would be for the output to be a series of pulses to a stepper motor controlling the hot water valve, with the valve being proportionally controlled and the differential between desired and actual temperature changes.

If one considers that there are hundreds of comfort control zones supplied by many fans with hot water boilers, electric water chillers, and steam or electric humidifiers, all with potential safety considerations (like the pilot light verification in a home furnace), then one can see that building system controls are complicated and dynamic, with constantly changing operating conditions throughout the building. Managing the control systems in the current environment of energy costs has become an important function. DDC systems are frequently called "energy management systems", although the control of sequences of operation is a necessity whether or not systems are operated economically.

Humidification

The psychrometric chart (Figure 108-2) is a tool for understanding the relationships between the various parameters of supply air and the relative humidity. This template allows a designer or operator to "work backwards" from a desired room relative humidity to the desired condition of the air as it enters the supply duct. Control of humidity is not required by most codes in all areas, but is for some in most geographic areas. The Uniform Mechanical Code (Uniform Mechanical Code, 2003) calls for OR relative humidities of 50%–60%. In a warm and humid climate, supply air can be drawn into a system and then exposed to cooling coils that drop the air temperature to 55°F. According to the psychrometric chart, if the relative humidity of the outside air is 80% and the outside air temperature is 85°F, when the air is cooled to 55°F, vapor will condense out of the air, and the relative humidity will be 100%. Then, if the air is heated to 70°F without the addition of water, the humidity will change to about 60%, according to the chart. In climates of low humidity, it is necessary to inject water vapor into the supply air to increase the humidity to the target level. This can be done with steam or other methods. Steam can be provided by steam boilers or electric steam generators that boil water directly.

Codes and Standards

Parameters for operation and maintenance of HVAC systems can be mandated by codes or can be designed on the basis of nonmandatory standards. Local jurisdictions probably will have adopted some national standards into their codes, such as the Uniform Mechanical Code and the Life Safety Code (NFPA, 2003). The JCAHO references some of the codes in the sections on the Management of the Environment of Care (JCAHO, 2000). For example, testing the control of supply air fans upon activation of some fire alarm devices refers the reader to the relevant standard, NFPA 90A, published by the National Fire Protection Association. (See Chapter 118.) Some of the building codes pertain primarily to the design of systems, rather than to their maintenance and operation. Hospital licensing laws might adopt and enforce some codes and standards or might simply incorporate some of the requirements of other documents. Because the applicable codes vary with location, no attempt is made here to provide a reference list for such documents. Starting with those codes referenced by the JCAHO is a good beginning. Design engineers in a particular can direct one to the applicable locally adopted building codes for HVAC systems. Chapter 120 addresses hospital facility safety standards.

Indoor Air Quality

For many years, the press and media gave much attention to the "sick building" syndrome. Stories discussed the exposure of occupants to toxic materials from new carpeting, and the contamination of air supplies by biological contaminants such as legionella and molds. "Indoor air quality" is the general term for the examination and control of the things that might be contained in the air inside a building. Any hospital facility operator has occasion to answer complaints or questions about indoor air quality from staff, patients, visitors, and physicians.

The first priority in considering indoor air quality is to ensure that no contaminants are introduced into the building from outside, or created within the building and systems and then spread by the HVAC systems. Generally, outside air quality is a known quantity, and if sufficient outside air is supplied to the building, the indoor air quality should be about the same, except that filtering will reduce some contamination (primarily particulate). The internal sources of air contamination include toxic chemicals, dust from construction work, airborne infectious contaminants from patients, and opportunities for biological growth within the ventilation systems. Isolation rooms are used to prevent pathogens from spreading through the air circulation system.

Toxic chemicals that are necessary in the delivery of health care have specific procedural requirements for such provisions as exhaust hoods, to prevent them from mixing with the internal air supply. Improper use or storage of chemicals can lead to impermissibly high exposures. Special smoke evacuation systems for some surgical equipment remove airborne particulates and aerosols from the operating room air.

Air handlers and adjacent evaporative cooling towers have the potential to serve as incubators of some biological contaminants. This incubation typically occurs where

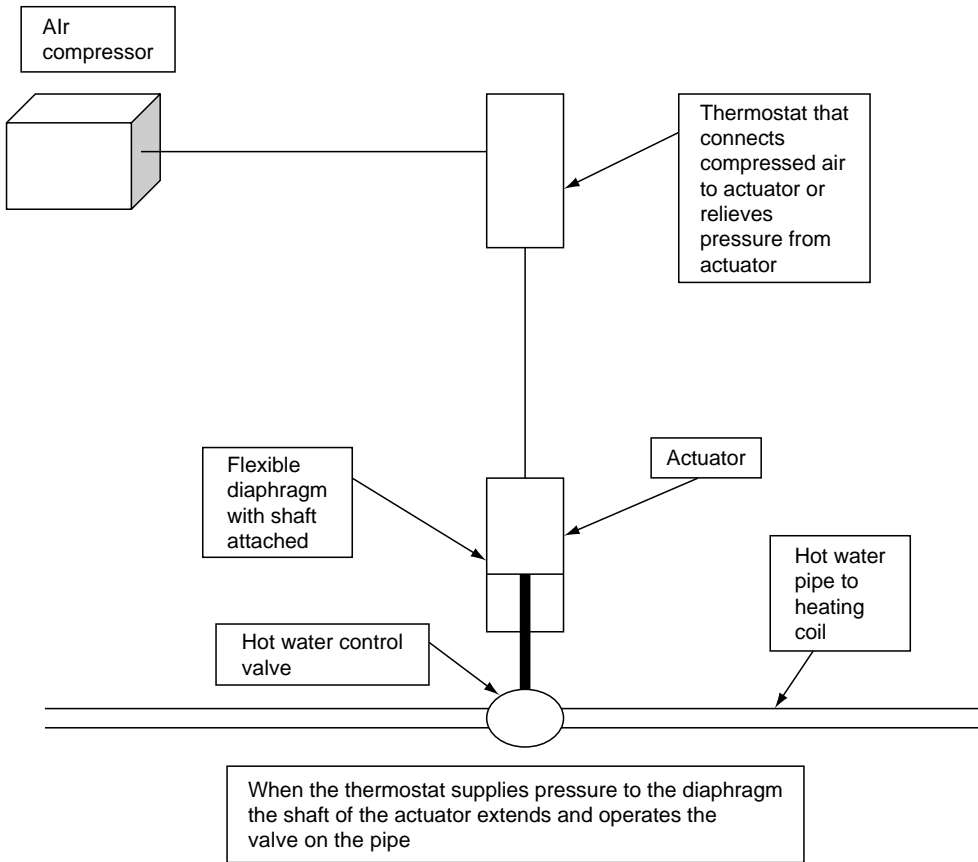

Figure 108-1 HVAC air handler.

Figure 108-2 Psychrometric chart.

standing water stagnates and chlorine or other agents degrade. Condensation collection areas in air handlers and refrigeration devices must be maintained and monitored properly, and in some cases treated to avoid unwanted biologic growth.

Some molds that are ubiquitous in soil and dust and that are usually harmless to healthy individuals can cause problems for ill patients. Current practice requires that construction zones within hospitals be kept at a negative pressure with respect to surrounding hospital areas, to avoid contamination of patient areas.

109

Electrical power systems have traditionally been regarded as falling within the province of the facilities engineering profession. However, there are several reasons for clinical engineers to be knowledgeable in this area. First, clinical engineers are increasingly involved in renovation and construction projects for health care facilities. The electrical power system is a key component of facility design, and a well-designed electrical power system is critical for the safe and effective performance of medical devices. Therefore, the clinical engineer must be cognizant of the major design issues and able to contribute to the design process. Second, in many health care facilities, the role of clinical engineering is expanding to encompass a wide variety of technological systems. Integrated management of technological systems in support of patient care is a role for which the clinical engineering professional is well prepared. Management of electrical power systems, including responsibility for system maintenance, can be a part of that expanded role. Third, clinical engineers are often called upon to investigate incidents in which a medical device or other technological system is suspected of having contributed to an adverse event. For example, investigation of incidents involving electrically powered devices may require consideration of the electrical power system. For this reason, it is important for clinical engineers to understand the design, function, maintenance, and clinical use of electrical power systems.

This chapter provides an overview of normal and emergency power systems, the two major categories of electrical power distribution in health care facilities. It also addresses isolated power systems that are used in some facilities. Basic principles are presented, along with references for further study.

Normal Electrical Power

Patient care increasingly relies on device-embodied medical technologies. The level of sophistication, number of products, and relative importance of medical devices have grown, placing greater demands on electrical power systems. These demands are not only for power capacity, but also for terms power quality and operational safety. The normal electrical power system in a health care facility distributes electricity provided by the community's electrical utility company. Although the utility company may give a limited degree of special consideration to health care facilities, the normal electrical power system is generally subject to the same quality and reliability issues affecting the larger community.

A qualified electrical engineer, in cooperation with the project architect, designs electrical power systems for construction and renovation projects. The primary role of the clinical engineer in system design is to provide information on the electrical requirements of any medical devices that will be used in the facility. When specifying the electrical requirements for medical devices, fundamental considerations include the voltage and current requirements of each device. This is a relatively simple issue for small, portable devices, but it is especially important to identify those medical devices that have more demanding requirements, such as imaging equipment systems.

Specification of the number and location of electrical outlets in a construction project might appear to be a minor issue. However, the number of receptacles is critical to accommodate not only the medical devices used today but also the number to be used in the future. The location of receptacles must be consistent with and supportive of clinical practice. Guidelines are available to help planners determine the number and location of electrical receptacles (AIA 2001).

Electrical Power

Matthew F. Baretich

President, Baretich Engineering, Inc.
 Fort Collins, CO

Additional considerations include requirements for quality and reliability of electrical power. Power quality involves such factors as voltage stability and the limitation of anomalies such as spikes, surges, dropouts, noise, and waveform distortion. Power quality can be particularly critical for certain analytical and imaging devices, and extensive testing may be required before device installation to determine the steps necessary to ensure adequate quality. The reliability of electrical power is addressed in the following section of this chapter.

Maintenance of electrical power systems is addressed in the JCAHO (Joint Commission on Accreditation of Healthcare Organizations) Environment of Care standards for Utility Systems Management (JCAHO 2002). Publications by the National Fire Protection Association (NFPA 2002b) and, for clinical laboratories, the College of American Pathologists (CAP 2002) offer additional guidance about system maintenance.

Emergency Electrical Power

Emergency electrical power systems are designed to provide power to critical devices and systems when power from the community's utility company is not available. To accomplish this objective, an emergency power system consists of an alternative power source and a means for distributing electricity from that source to critical devices and systems.

Identification of critical devices and systems to receive emergency power is an important design function for clinical engineering. A comprehensive list of critical devices and systems ranges from life-support equipment, such as ventilators, and essential utility systems, such as medical air compressors, to safety and emergency systems, such as egress path lighting. The JCAHO Environment of Care standards (JCAHO 2002) provide a minimum list of emergency functions and areas to be included on such a list (Standard EC.1.7.1). However, development of a comprehensive list is a multidisciplinary process incorporating clinical and technical perspectives.

In some cases, a local battery-powered uninterruptible power supply (UPS) protects a critical device. However, NFPA standards (NFPA 2002a, NFPA 2002b) require certain health care facilities, including hospitals, to provide an essential power system that includes a centralized power source and a distribution system meeting stringent design criteria (NFPA 2002c).

Although some health care facilities are considering power sources of a more exotic nature, such as kinetic energy (flywheel) systems, fuel cell systems, and small gas turbine motor generator systems, the power source in most cases is a reciprocating diesel engine motor generator set. When power from the community utility company is lost, the motor-generator set starts automatically. Once the generator's voltage and frequency have stabilized at the appropriate level (generally within a few seconds) an automatic transfer switch (ATS) disconnects a portion of the facility's electrical power distribution system from the utility company lines to the facility generator.

Key design issues for the emergency power system include: The capacity of the motor-generator set and associated switchgear and the selection of circuits from the facility's distribution system that will be transferred to the generator. These issues depend, in turn, on the number and location of devices and systems that require emergency power and on the electrical requirements of those devices and systems. These are areas in which clinical engineering is key to the facility design process.

JCAHO Environment of Care standards (JCAHO 2002) include detailed requirements for testing and maintenance of emergency power systems (Standards EC.2.10.4 and

EC.2.10.4.1). Maintenance requirements are also addressed in NFPA publications (NFPA 2002c). Monthly testing of the motor generator set and associated switchgear remains at the heart of the maintenance program. When open transfer switchgear is used, a brief dropout of power occurs as emergency circuits are transferred from the community utility company to the generator and back (at the end of the test period). Closed transfer switchgear eliminates this power dropout and is preferred in new installations.

JCAHO Environment of Care standards (JCAHO 2002) also address emergency power systems as part of the facility's emergency management plan (Standard EC.1.4) and educational program (Standard EC.2.8). Clinical personnel need to know how to respond in case of an electrical system failure. In the most likely scenario, power is lost on normal circuits but continued (with a few seconds of delay) on emergency circuits. In this scenario, it is important for emergency circuits to be readily and consistently identifiable throughout the facility. These circuits are typically identified with red receptacles and/or cover plates. In a more serious scenario, the complete loss of electrical power occurs in all or part of the facility (when power is unavailable from either the community power utility or the facility's emergency power source). In this scenario, it is vital to have manual procedures and equipment in place to provide basic patient care. Planning for either scenario should be multidisciplinary and should include clinical and technical perspectives.

Isolated Power Systems

The isolated power system (IPS) is a three-wire power distribution system with one ground conductor and two power conductors that are isolated from ground. In an ideal IPS, no current would flow in a connection from either power conductor to the ground conductor. In a real-world IPS, the potential for current flow from either power conductor to the ground conductor is limited by design and is continuously monitored for deterioration.

Isolated power systems were developed as a means to reduce the risk of explosion in anesthetizing locations housing flammable anesthetics. In conjunction with conductive flooring to minimize build up of static charges and explosion-proof electrical receptacles to prevent explosions, isolated power systems reduced the likelihood of electrical sparks that could ignite explosive vapors. With the pervasive use of nonflammable anesthetics in current anesthetic practice, this rationale for isolated power is primarily of historical interest.

Isolated power systems are applicable in settings where the limitation of current provides an important measure of safety. NFPA standards (NFPA 2002b) require health care facilities to identify any "wet locations" in which the potential for ground currents must be controlled. The standards define a "wet location" as: A patient care area that is normally subject to wet conditions while patients are present, including standing fluids on the floor or fluids drenching the work area, either of which condition is intimate to the patient or staff (Section 3.3.179). Routine housekeeping procedures and incidental spillage of liquids do not define a wet location (Section A.3.3.179).

Many hospitals identify hydrotherapy rooms as wet locations. Although it is a matter of considerable controversy, some hospitals (notably, the Veterans Administration Health System hospitals) identify their operating rooms as wet locations.

In areas identified by the health care facility as wet locations, NFPA standards require the use of devices to limit the potential for current flow to ground. One option is to use

ground fault circuit interrupter (GFCI) devices. However, since GFCI devices interrupt power when they detect excessive current to ground, they can be used only in areas where interruption of power is acceptable. For example, a hospital that identifies its hydrotherapy rooms as wet locations might install GFCI devices to protect patients and staff because it has determined that interruption of electrical power in this area is acceptable.

On the other hand, interruption of electrical power in an operating room is clearly unacceptable. If a health care facility identifies its operating rooms as wet locations, then GFCI devices are not appropriate and an isolated power system is required. Therefore, it is important to consider carefully whether or not the definition of wet location represents actual conditions within the operating rooms.

Whether or not to install an isolated power system is a critical design issue, and the initial decision in the construction of new operating rooms. The facility might wish to conduct a risk assessment to determine whether the installation costs, maintenance costs, and operational complexity for clinical and technical personnel associated with an isolated power system will produce a net benefit in terms of patient and staff safety. Maintenance of an isolated power system includes regular testing to confirm that the actual level of isolation meets appropriate standards and that line isolation monitors (LIMs) are functioning correctly. It is important for clinical personnel (such as operating room staff) and technical personnel, (such as the clinical engineering staff) to understand the function of isolated power systems. In particular, it is important to establish policies and procedures for staff response to LIM alarms.

Summary

Clinical engineers should take active roles in the designs of health care facilities, including contributions to the design of electrical power systems. They also should adopt a broad view of their roles and should apply their expertise to the entire spectrum of technological systems supporting patient care.

William Frank

Medical Gas Services, Inc.
Webster, NH

Few data have been published about maintaining an existing medical gas system. As with most mechanical systems, common sense is a prerequisite, as are adequate manpower and tools. Unfortunately, the maintenance of health care facilities appears to be in decline. Medical gas systems pose a unique problem because the gases that leak from them cannot be seen or smelled. It is too late by the time leaks are audible, and repairs are significantly more costly by then. This chapter should encourage attentiveness to the financial savings and improved patient care that result from a medical gas system maintenance program. The following material is based primarily on first-hand experience.

History of Medical Gas Systems

In the late 1940s and early 1950s, health care workers recognized the hazards of moving heavy high pressure cylinders to various locations. Cylinders were placed in closets, equipped with a pressure-reducing regulator, and rubber hoses or soft copper tubing was run to several rooms. The terminal end was a valve from an oxy-acetylene torch, equipped with a flow meter. When oxygen was not needed, the torch valve was turned off, just like a water faucet. This arrangement was greatly improved when gas cylinders were connected by way of a common manifold, and use points were increased. Outlets and connectors were designed and manufactured by companies including NCG, Ohio Medical, Puritan Bennett, Oxequip, and Schrader. Some connectors were of the screw-on type, incorporating the diameter index safety system (DISS). Some were the "quick connect" type. Initially, any gas could be plugged into any outlet, but this meant that inappropriate gases could be connected.

In some instances, the volume of oxygen used justified the need for an oxygen generator in the hospital, and a large bank of high pressure cylinders was used as a reservoir. When the pressure neared depletion, the generator was started to refill the cylinders. Central piping systems using unclean copper pipes were installed, crude by today's standards. In most cases, the pipe was soft drawn and soft soldered at the connections. Blinking red light bulbs indicated pressure problems.

When the problems with portable suction pumps and cross contamination were recognized, central vacuum systems were installed, and the other gases, nitrous oxide, and medical air all followed suit in using these systems. National Fire Protection Association Standard NFPA 56F (now NFPA 99) became the standard for installation of medical gas systems.

Uses of Medical Gases in Patient Care

Some medical gases used in patient care include the following:

- Oxygen: Administered directly to patients via cannula, blenders, aerosol tents, ventilators, anesthesia machines, hyperbaric chambers, and other methods.
- Medical air: The oxygen used in patient care.
- Nitrous oxide: Administered via anesthesia machines, along with oxygen and various anesthetic agents.
- Carbon dioxide: Primarily used in open heart surgery and laparoscopy procedures.
- Nitrogen: A gas that drives various orthopedic tools and tourniquets.
- Vacuum: Not a gas, but this device provides the means for suctioning patients and for anesthesia waste gas evacuation.

"My suction doesn't work . . . do something!"

Medical vacuum systems are not complicated, yet they are often misunderstood and abused. The purpose of a vacuum system is to provide sufficient flow, at a negative pressure, to move fluids from the patient into a collection bottle. It generally consists of a pump system, a receiver for storage of vacuumed gases, piping, shut-off valves, and sometimes alarms and outlets or terminals. Secondary control equipment is attached to the terminals. Successful operation depends on flow rates under negative pressure. Flows diminish if any portion of the system becomes obstructed or is undersized, or if the pumps

are worn or undersized. Frequently, the pump vacuum switch settings are adjusted because of flow problems, causing the pumps to operate at higher negative pressures, with minimal increase in flows. In addition, diminished flow occurs when terminals are added to the system with no consideration for existing pump or piping system capacities.

By far, the greatest flow problems that the author has encountered are associated with the terminals or secondary equipment. NFPA 99, paragraph 4-10.1.1.3, requires new vacuum terminals to have a minimal flow rate of 3 cubic feet per minute (cfm) with a pressure of at least 12 inches of mercury ("Hg) at the nearest adjacent terminal. In a properly designed system, new terminals easily attain this flow rate. Many older terminals cannot flow 3 cfm because of flow-restrictive components and passages. At best, the flow rates may be 1 to 2 cfm. The most important fact is knowing what terminals are capable of flowing at normal negative pressures and ensuring that all similar terminals yield those flows.

Causes of Low Flow Terminals and Corrective Actions

- Debris or improper parts in terminals. Disassemble, clean, and rebuild with proper parts and new seal rings. Leaking seal rings behind the faceplate draw in atmospheric air rebuild terminal with new seal rings.
- Body fluids that have been drawn through the terminal and into the riser. Flush with hot, soapy water. Repeated attempts at flushing will either remove the blockage or prove that the blockage has solidified. If flushing is not successful, the line probably will have to be replaced.

Tips on Flushing

There must be some flow to draw the solution into the terminal and riser. Try hot, soapy water. Good results have been obtained with a product called "sani treat," manufactured by Pascal Company. It comes in a concentrated form and is used in dentistry.

If there is a shut-off valve, draw some solution through the terminal into the riser. Close the valve and let the solution work for 10–15 minutes. If the blockage dissolves, one hears the increased flow when the shut-off valve is opened.

The author has seen old systems that are so full of solidified fluids that 3/4" laterals were reduced to the size of a pencil. Typically, such solidified fluids accumulated over many years ago when body fluid was drawn from the patient into the terminal without the use of a collection bottle.

Failure to shut off regulators when they are not used for patient care is a common abuse of vacuum systems. A suction regulator usually controls the amount of flow required to suction a patient. Contrary to most opinions, liquid should not flow through the pipes into the receiver. Liquid should remain in the canister. If liquid enters the terminals, the moisture evaporates leaving a powder-like residue that usually causes blockage in 3/8" and 1/4" risers. The author has found no obstructions in 1/2" and larger risers.

Various cylinder gas mixtures are used in pulmonary function testing and blood gas analysis. Quality standards for medical gases are found in the compressed gas data book published by the Compressed Gas Association, as well as in the United States Pharmacopeia.

System Components**Sources**

Sources are devices that produce or control the flow of medical gases through the piping network.

Bulk Systems

Bulk systems for oxygen, nitrous oxide, and carbon dioxide consist of special insulated vessels, vaporizers, and regulators. They have reserve systems and are wired to master alarms. These systems can be constructed with cryogenic vessels or a high pressure manifold, depending on usage. Typically, oxygen, nitrous oxide, and carbon dioxide are supplied to large facilities in cryogenic tanks.

Manifolds supply nitrogen, nitrous oxide, air, and carbon dioxide in high pressure cylinders may be found in smaller hospitals.

Cryogenic vessels are equipped with ambient air vaporizers that convert the liquids to a gaseous state before they enter the pipeline.

Manifold and bulk tanks are equipped with regulators to control the pressures, reserve systems, and pressure switches wired to master alarms.

Vacuum Pumps

Vacuum pumps are mechanized devices that create a negative pressure in the piping system. Use of a receiving tank allows for storage, which permits the pumps to cycle on and off rather than run continuously. Systems should be sized according to number of outlets and use factors. Larger facilities might have several pump systems or multiples of two or more pumps.

Medical Air Treatment Systems

Medical air treatment systems are usually two or more compressors equipped with a receiver, drivers, regulator, filters, dew point monitors, and carbon monoxide alarms. Unlike other medical systems, where usage varies only slightly, medical air usage is erratic in many hospitals. This often results in elevated dew points in low-use areas an occasional "stale" odor.

Piping Networks

Piping networks in most medical gas systems are a mixture of old and new pipes. Some facilities still have combinations of soft solder and silver solder joints, while the new sections have brazed joints. Although the replacement of existing pipes is usually an economic decision, it is wise to have all piping properly labeled with color-coded labels and flow arrows.

Valves

There are two categories of valves in piping systems. Zone valves are placed on corridor walls and should be labeled to indicate the rooms that they control. If in doubt, verify the areas controlled prior to labeling.

Service valves are valves in concealed areas such as pipe chases or in the ceiling, and have been a source of fatalities. NFPA 99 has specific labeling instructions for service valves, including that all valves should be verified to determine exactly what they control prior to labeling.

The following are several case histories of fatalities resulting from a lack of attention to medical gas system valves.

"Mystery of Turned-Off Hospital Oxygen Supply Solved by Denver Police" (Biomedical Safety & Standards, 1987)

"The holiday season at the children's hospital in Denver was marred by an unpleasant mystery. How did the hospital's main oxygen valve get turned off, and did the deaths of two babies in the neonatal intensive care unit (NICU) result from this act? The initial investigation was conducted by hospital-shared services of Colorado. Denver Police Chief Tom Coggan complained that the security service was slow in reporting details to the police.

Biomedical Safety & Standards® contacted the Denver police and the district attorney's office. Chief Deputy District Attorney Chuck Lepley explained the sequence of events. The main oxygen valve was located in a small room, which was kept locked. The room also was used to store laundry, and several employees had access to it. Police investigation revealed that one employee decided to eat his lunch there on November 29. Becoming warm, he turned off what he thought was a heater valve. When he noticed that the temperature did not go down, and when he heard alarms and people rushing about, he left the room apparently in panic. The hospital's chief engineer turned the valve back on. The hospital employee eventually confessed his actions to the police. District Attorney Lepley told this newsletter that his office determined there was no criminal intent. Reportedly, the hospital has now installed a protective box around the valve.

Although the oxygen had been off for approximately 15 minutes, 19 babies in the NICU were deprived of supplemental oxygen for only about two minutes before backup oxygen was established. During this two-minute period, the babies were breathing room air. One infant, with serious congenital abnormalities and lung disorders, died three days later on December 1. Another infant, also inside an incubator at the time of the accident, died on December 2. Shortly thereafter, two more babies in the unit died, but neither had been in an incubator at the time of the accident. While there remains the possibility of litigation by the parents of the infants involved, District Attorney Lepley told this newsletter that his office currently had no evidence linking any baby death with the incident.

Another question in the case is why the initial investigations were not reported to the police earlier. Detective Marcus Chavez of the Denver police told this newsletter that hospital shared services has been cited for failure to report the incident, which is in violation of a city ordinance. Currently, there are no Colorado regulations that require health care facilities to report unexplained deaths to state health officials. However, some proposed regulations are being considered by the legislature. Index: Oxygen shut-off, hospital, accident."

"Hospital's Oxygen Cut; One in Coma" (Boston Globe, 1995)

"Melbourne, Florida—The wrong valve on a hospital's oxygen line was close on Monday, cutting off some patient's oxygen supply for 10 to 15 minutes, hospital officials said. One woman remained in critical condition yesterday.

The 55-year old patient, whose name was withheld at her family's request, was among 56 patients at Holmes regional medical center whose supplementary oxygen supply was interrupted early Monday.

"At this point, her prognosis is not good," Valerie Davis, a Holmes spokeswoman, said yesterday. "We don't necessarily anticipate a recovery, but it's too early to tell."

Nurses alerted by an oxygen pressure alarm distributed portable oxygen units, but the woman went into cardiopulmonary arrest, said Mike Means, Holmes chief executive officer, said Tuesday.

The other patients suffered no adverse effects, Means said.

Staff members had planned to shut off oxygen only to the hospital's east wing for a routine construction project. Instead, a valve was closed that shut off oxygen to the east and west wings, hospital officials said.

"This was a purely human error," Means said at a news conference Tuesday.

Though he did not turn the valve, the hospital's director of engineering, Glen E. Anderson, was reassigned and later submitted his resignation.

The hospital would not identify who turned the valve. "This was a team failure," means said. "I don't want anyone to accept total responsibility."

The shut off did not affect patients on life support and respirators, only those in the west wing needing supplementary oxygen, said Dr. Richard Baney, the hospital's medical director. Many of the patients were recovering from surgery or suffering conditions such as pneumonia.

The hospital said the woman, who was made comatose, had been recovering from surgery."

"Woman Dies after Hospital Error" (Concord Monitor, 1995)

"Melbourne, Florida – a woman died four days after a maintenance worker accidentally shut off her oxygen and put her in a coma.

The 55-year-old woman died Friday at Holmes regional medical center after her family requested that life support systems be disconnected, hospital officials said.

The woman, who was recovering from orthopedic surgery, went into cardiac arrest last Monday and never regained consciousness after the worker accidentally turned off a valve that cut off her supplemental oxygen supply.

The mistake also left 58 other patients without backup oxygen for up to 15 minutes. None of them suffered ill effects.

A hospital spokeswoman blamed an unidentified veteran maintenance worker who misread part of a construction project plan."

Older valves in these systems pose a problem during renovations; many no longer seal, and must be replaced.

Master Alarms

NFPA 99 specifies which signals must be in the panels and how they must be wired. These alarm points monitor the main gas lines and source conditions. Normally, the suppliers of cryogenic vessels test their alarm functions annually, but they do not test pressure switches inside the facility. It is the responsibility of every facility to test all master alarms.

Area Alarms

Area alarms, which monitor conditions in specific critical care areas, are found on alarm panels. NFPA 99 has specific requirements for locations and signals. Both area and master alarms should be reviewed to determine whether they are serviceable, whether parts are available, whether all signals alarm, and whether sensing switches exist.

Outlets and Inlets

Outlets are points at which connections can be made to the medical gas piping system to supply gases under pressure. Inlets supply vacuum. There are two styles of connections: Quick-connect and "twist-on." Quick connections are "plug-ins." The author has observed outlets sagging out of the wall from the weight of the equipment connected to them, which presents a safety hazard. Many of the old outlets do not provide the higher flows required by NFPA 99. Some can be updated, and some can not. Some manufacturers no longer exist. All outlets should be listed by make and model on an inventory list to ensure that parts are available.

Secondary Equipment

While hoses, flow meters, and vacuum regulators are not part of the pipeline system, they can contribute substantially to gas and vacuum consumption. These items should be checked as part of routine inspection procedures. Often, no single department seems to be responsible for inspecting them for either leakage or function. An emulsion of soap, water, and glycerin can be used to check for leaks in flow meters and fittings.

Anesthesia hoses are not considered part of the anesthesia machine's preventive maintenance, and are not usually tested during machine maintenance. It is not uncommon to find vacuum regulator seals completely missing, with the regulator pulling 3 cfm through the outlets.

System Maintenance

Periodically, one hears such phrases as "follow the manufacturer's instructions" and "follow NFPA 99 guidelines." One should not confuse initial certification with ongoing maintenance. Medical gas systems are dynamic, not static, and as with most things, the older the systems become, the more likely it will be to deteriorate and require increased attention, maintenance, and repair.

Medical Gas System Inspection Methodology

The purpose of an inspection is the following:

- To determine whether systems and components perform as designed, are leak free, and are functionally safe for patient care

- To provide unique inventory and location of all components
- To provide short-range and long-range summary conditions

Short-range conditions mean that problems should be addressed within 12 months, such as repair of leaks and verification and labeling of zone valves and alarms.

Long-range conditions mean items that require capitol budget money, such as the installation of medical air system monitors and alarms and the replacement of obsolete alarms and manifolds.

Testing Protocol

Bulk Systems

Document the main tank and reserve pressures, conduct a leak test of the piping on a pad, and recommend improvements.

Manifolds

Document a leak test on all components, record pressures, and recommend improvements.

Vacuum Pumps

Document time and pressure cycles, record pressures, and recommend improvements.

Air treatment systems

Document the location of the intake pipe document time and pressure cycles, record pressures, and recommend improvements.

Zone valves

Document an external leak test, and conduct an internal leak test with permission of department head.

Outlets

Document the model and manufacturer, check functions of latches and labels, check for external leaks and flow rate.

Master Alarms

Document the location of all master pressure switches and the location of all main service valves. Conduct testing only with hospital personnel present.

Area Alarms

Document a test actuation if permitted by hospital personnel.

Particulate Contamination and Remedies

Many systems have particulates in various forms, such as pink or black copper oxide, copper chips, and decayed "O" rings, which can usually be removed by high pressure, high-flow purging. When any existing lines are cut for expansion, they should be thoroughly purged prior to brazing in new sections.

There are as many descriptions as there are types of dirt in the lines. Terms such as "particulates," "contaminants in solid form," "dirt in the lines," and "foreign material" are frequently used. The author has encountered a wide variety of contaminants including lumps of soft solder, flux, mud, copper chips, copper oxide, and gray and black dust.

Detecting the Problem

The following tips can help detect particulate contamination in a piping system.

- Look for dirt in the anesthesia machine; in-line filters.
- Look for dirt in flow meters; look at the needle valve and seal rings.
- Look for dirt after purging outlets at maximum velocity into a white cloth.
- Check inside blenders for presence of dirt.
- Examine the 5 micron filters on volume ventilators.
- Disassemble the first outlet in any system and look for debris. Cover the body opening with white cloth—a face cloth will do. Then, open the zone valve for 5 seconds. Hold the cloth firmly or it will blow away. Look for stains. Reassemble the outlet. Repeat the procedure at the last outlet on that lateral. If debris is found, purge the pipe clean as previously described

Purging

The author has successfully purged systems with cryogenic source nitrogen at a pressure of 90 psi on all gases except air. However, in order to be done effectively, the outlets should be rebuilt. Significant amounts of dirt are often retained in the seal rings, springs, and pistons. The rebuilding process should be done sequentially from the first to last outlet to drive the dirt to the last outlet. If the dirt does not come out at 90 psi, and maximum flow, it will not break loose unless you pound on the pipes.

Water Sealed Pumps

Water sealed pumps pose a different problem. Minerals from untreated water leach out in the air stream after the drier. Unless the system has good filtration, the minerals migrate

throughout the system, usually appearing first in clinical areas of heavy ventilator use, such as the intensive care unit (ICU) and neonatal intensive care unit (NICU).

A gray or white powder begins to occlude the 5-micron filter on the ventilator. What happens to blenders, aerosol tents and incubators? The author is aware of several systems with the distinct odor of chlorine in the air systems. They can be purged in the same way as other pressure systems, but filtration must be installed to prevent a recurrence.

Certified Systems

Problems may occur in newly installed and "certified" systems. If the testing company used industrial air sampling techniques (i.e., 10 lpm for 10 min = 100 lpm, instead of 100 lpm flows) the presence of undetected contaminants is likely.

Renovations and Modifications

When adding to an existing system, thoroughly purge the existing line before connecting to the new pipe.

Outlet Seals

Seal rings in outlets will dry out due to the dry gases. The only way to determine system leakage is with a pressure test, which is more than closing a zone valve. For a true pressure test, drop the pressure below the line pressure. Otherwise, a pressure loss will not be detected if the valve seal leaks. Be sure to remove all the secondary equipment when performing pressure tests, or else the leaks can not be identified. The common practice of having equipment attached to all outlets at all times, causes early failure of the front seal ring, but this failure is only evident when the equipment is disconnected.

Conclusion

Medical gas systems can be appreciated as life-support systems, drug dispensing systems, and utilities to be conserved. Patient deaths have resulted from failure to adequately control, maintain, and repair medical gas systems. Few facilities track the amounts that they pay for gas products versus the amounts that they actually use, and such inattention drains financial resources.

Common sense should dictate any gas maintenance program. JCAHO has always called for that "unique inventory." In 1987, JCAHO described some specific maintenance steps, such as pressure testing and flow rating. Clinical engineers should know what kinds of system components exist (e.g., outlets or alarms) and what type of maintenance they require, taking frequency of maintenance and parts inventory into consideration.

Support Services

Nicholas Cram

Texas A&M University
College Station, TX

Jobs that fall under the heading of support services vary according to facility location, budget, size, and mission. Normally, support services are those services that are not clinically required, but are essential for efficient operations and improved clinical outcomes in a facility. Support services include both blue-collar and white-collar jobs. Examples blue collar support services include plant operations, maintenance and general engineering, laundry, housekeeping, dietary and food handling, and landscaping and volunteer services. White collar support services include human relations, social services, mail room organization, purchasing and receiving, employment, education, pharmacy, medical records, laboratory, administration, spiritual focus. In addition, technical support services include clinical engineering, telecommunications and private broadcast exchange, information services, and electronics and video support. Also, infection control services, quality management, and regulatory and legal affairs could be considered types of support services. If a facility were associated with a university, it would have an academic category with its own support services.

Health care costs could be reduced if support services were automated or run more efficiently. Essentially, support services are hospital employees not directly involved in patient care. The term "team nursing" was introduced by visionary nurses more than ten years ago (Alfaro-Lefevre, 1999). The concept suggested that everyone had multiple job functions, and instead of waiting for their specific task to appear, team nurses were continually occupied with tasks, with patient care their priority. The morale was high, and the work environment was jubilant. If it worked so well, why was it discontinued? Some nurses felt they were being overworked and failed to see the overall picture of better outcomes, less haphazard behaviors, and more empowerment, which resulted in lowered employee absenteeism, fewer needle sticks, and a pride in their work due to the team effort. The disadvantage of team nursing is that everyone becomes a generalist. American medicine has prided itself on becoming increasingly subspecialized, almost to a point where one physician cannot discuss an entire case with a non-specialized physician.

Undoubtedly, as a clinical engineer, the opportunities to augment patient care due to a specialized, separatized evolution are enormous. Clearly, support personnel must be downsized and/or educated for more challenging tasks. The clinical engineer is the natural educator in this environment because he has a clear knowledge of what must be done. Every automated task that places the nurse at the patient's bedside improves patient care. According to the United States Bureau of Census (2002), the United States will need approximately 500,000 nurses by 2020. Accordingly, a medical device or medical transmission system (such as telemedicine) that efficiently allows a nurse or other clinical specialist to care for additional patients without clinical risk will be one response to the rapidly worsening health care crisis.

Hospitals have become complex electronic facilities requiring specialized engineers to help them function without any down time (i.e., time when a machine cannot be used).

Common boards for similar transducers will lower the cost of repair, and auxiliary equipment will also become more complicated, serving larger numbers of patients and requiring more training to maintain and operate.

In addition to changes within the hospital environment, external changes will encourage the use of convenient home telemedical care. The health care specialists will not wait for the patients to walk into their clinics; specialized ambulances will be dispatched to care for the swarm of aging babyboomers who will have a significant impact on health care resources. For this affluent generation before them, any medical process, service or device that makes life more convenient will be a success.

The days of huge support staffs for hospitals may be a thing of the past along with the 500–1000 bed hospital. Health care must compete commercially to survive, and the current health care model must change as well in order to do so.

Director Plant Operations Maintenance & Engineering (POM&E)

The typical POM&E director has an educational background in construction science or mechanical engineering with a salary of \$65,000–\$100,000/year depending on location, expertise, responsibilities, and the number of team members supervised. Responsibilities

include the overall building and grounds, HVAC (heating, ventilation, and air conditioning), electricity, water, hazardous waste disposal, fire safety, and the general maintenance of the building. The job is similar to that of a mayor operating a small city.

Laundry Supervisor

The supervisor or director of laundry usually learns on the job and has a high school diploma or graduate equivalent degree (GED). The laundry supervisor is usually promoted from within the pool of salaried blue-collar workers in the hospital system. Salary commensurate with experience ranges from \$28,000–45,000 per year. Systems that contract out laundry services will place someone with a bachelor's degree in this position to gain managerial experience. In some hospitals this is a preparatory assignment as the employee moves up the management chain.

Housekeeping

The supervisor or director of housekeeping usually learns on the job and has a high school diploma or GED, similar to the laundry supervisor. The housekeeping supervisor is also usually promoted from within the pool of salaried blue-collar workers in the hospital system. Salary commensurate with experience ranges from \$28,000–45,000/year. This is another training ground for contract services, and most hospitals place someone with at bachelor's degree in this position to provide exposure and managerial experience. This assignment, as with the laundry supervisor, is often a preparatory assignment as the employee moves up the management chain.

Dietary

This is sometimes considered a clinical job, since most dieticians now earn a master's degree or graduate degree in nutrition and physiology. A dietician is given parameters of calories, proteins, and carbohydrates that a patient is allowed to consume. In addition to planning a healthy diet with the appropriate amounts of minerals and vitamins, the dietician also attempts to make the meal visually and gastronomically pleasing. Salaries vary greatly depending on experience and education, as well as the priority the hospital administration places on the position.

Food Handlers

Cooks, servers, food stores, and management make up the bulk of positions in the food-handling department. Many hospitals take great pride in hiring the best chefs and in serving meals that are competitive with local delis and restaurants. The priority the administration places on this department by determines the salaries, but the hospitals generally pay better than the local fast-food chains, their major employee drain.

Landscaping and Groundskeeping

This area requires little skill or training unless the hospital is a high profile, large, or well-known facility associated with an academic institution. Landscaping and grounds-keeping duties are usually managed under POM&E or contracted out. This area presents an opportunity for a third-party outsourcing group employee to move up the management chain, but it is more difficult to move up than with laundry or housekeeping. This work may be seasonal, and hospitals often employ high school students for labor, and college students as managers.

Volunteer Services

Many hospitals could not function if community volunteers did not devote hours of service to the hospital. Many volunteers are former hospital employees who find gratification through giving back to their former employers. The baby boomers provide more volunteer services than any previous generation (US Bureau of Census, 2002). Volunteers usually answer phones; deliver books, newspapers, and videos; and work in the hospital library. Some volunteers walk with patients who require daily exercise, chatting with them and lifting their spirits. Volunteers also operate hospital gift shops and information desks, and those with expertise can enter patient information forms into the main server. With more baby boomers retiring, hospitals can anticipate even more help, which might somewhat check the loss of nursing, clinical, and technology positions.

Human Relations

The human relations, or human resources (HR), department provides stability in hospital employment and maintains policies that preserve the legal liability of the hospital from civil and criminal actions. The goal of all human relations departments should be to maintain a joyous workplace and ensure that employees are paid in an appropriate and timely manner. This goal is idealistic; however, HR departments are beginning to realize that a good work environment maintains employee longevity better than bonuses. Some hospitals still provide bonuses to attract employees, which causes a pattern of turnover and resentment among those who have remained loyal to their current hospital. As soon as the contract period ends, the bonus employee looks for the next bonus. An attraction bonus paid out as a 401(k) after 5 years, and again at 10 years, might better serve the hospital. The author has heard HR directors comment that this plan would attract fewer employees. Although this could be true, the commitment obtained would end the bonus cycle.

Social Services

Many customers who are treated at hospitals cannot pay for their treatment(s). This situation has created a two-tiered hospital system in the United States known as "for-profit" and "not-for-profit" hospitals. Not-for-profit hospitals are usually affiliated with a religious sect and have a commitment to turn no one away who needs healing, in keeping with the teachings of St. Francis. For-profit hospitals run their hospitals like a business and have shareholders to finance growth. Everyone who enters a hospital must be cared for and stabilized before they are released, according to the provisions of the Emergency Medical Treatment and Active Labor Act (EMTALA).

Whether for-profit or not-for-profit, certain help must be provided to all citizens. Finding care and housing for patients and families is the responsibility of the social services department. Social workers have at least a bachelor's degree, and their aids may hold an associate's degree. Salaries tend to be lower than those for other white-collar jobs.

Mail Room

A health care system is much like a small city, with all attendant services, including mail delivery. Most correspondence takes place by way of the Internet, telephone, voicemail, and pager, but typewritten, handwritten, and word processor generated communications still must be delivered within and outside the hospital. This process is sometimes a responsibility of volunteer services or long-time employee of the hospital. A misdelivered or undelivered piece of mail could be catastrophic. This position generally falls in the medium pay range.

Purchasing, Receiving, and Warehouse

Every item that is bought, received, and stored must have a transaction with the purchasing and receiving department and the warehouse department. In large facilities, these areas are comprise two distinct departments. However, they are often combined, because the ordering, handling, and storage of goods is usually done in one process, and reporting to a single director makes tracking easier. Department directors have discretion to purchase inexpensive items in order to keep normal hospital processes flowing. Expensive items must be reviewed by equipment and budget committees and approved before they are purchased. Managing this dynamic department is similar to managing a Wal-Mart or other large multi-department franchise. The primary difference is that all orders are processed on a computer, and no customers walking through the front door. Most transactions occur via fax, phone, or e-mail.

There are several levels of management in this department. The director of a large group of facilities is well compensated, and the position requires at least a bachelor's degree in business or advertising, and possibly a master's in business administration.

Employment Office

Most employment offices are a division of the human relations department. However, many facilities have split off the employment office as its own department because finding qualified personnel, reviewing references, and interviewing prospective candidates has become so demanding. This separation allows the physical building to be located

away from the congestion of the day-to-day hospital operations. Usually, several associates recruit clinical personnel such as intensive care nurses, or other specialized categories of employees. This job may seem like that of a telemarketer, but the personal fulfillment can be very rewarding. The department director should have a bachelor's degree in marketing or business. Salary depends on the size of the organization and the demands to fill certain positions.

Education Department

The education department is responsible for educating the staff and the patients about the health care facility. All clinical team members must have annual training to keep their life-support skills current and accurate. All clinical and non-clinical employees receive testing and training about fire, waste management, infection control, local and external disaster, and security annually. The education department is responsible for documenting and coordinating all of these activities.

Pharmacy

The pharmacy maintains all medications, including oral (those that are swallowed, such as pills or syrups), external (those rubbed on the skin, creams and ointments), intravenous (those given with sterile tubing and/or a syringe), sprays and drops for the nose and eyes, and suppositories (those that are placed in the rectum). Certain medications are not pre-manufactured, and must be prepared in a sterile environment using specific calculations. Aside from dispensing medications for patients, pharmacists also check for drug interactions, when one drug given to a patient taking one or more other drugs will cause an unwanted effect or chemical interactions, when the chemistry of one drug may disable another drug. Pharmacists also check the dosages of drugs prescribed by physicians to ensure that they are within an appropriate range. Pharmacy technicians assist the pharmacist in filling physician orders and delivering medications to the patients. A pharmacy degree is a six-year degree consisting of five years of classroom training and one year spent working with a mentor. There is a shortage of pharmacists due to the rigorous demands. Pharmacists may earn as much as \$75 per hour and command a \$5000-10,000 sign-on bonus.

Medical Records

The medical records department is rarely seen or known unless except among those who work in health care. Every medication, nursing, or physician procedure and/or surgery is recorded in the medical record. Entire laboratory tests, diagnostic tests using medical devices, and physician-nursing, physician-physician consults appear in the medical records. Different states have different requirements as to length of time medical records must be maintained. Most states require at least 15 years retention. Due to the immense amount of information created in just one medical visit, the medical records department stores records on compact disks. Voice recognition and other storage and retrieval technology, now available and widespread in the commercial sector, will soon be affordable enough for all medical records departments to translate physician records and to store their contents on a server-like network. Many people working in the medical records department have clerical type jobs, while others have associated managerial tasks and report to the director of medical records.

Clinical Laboratory

Few departments have embraced new technology to the extent of the clinical laboratory. Better and more accurate tests, along with cheaper and faster results have resulted in an automated, assembly line-like lab environment. Each department in the lab has a specialist responsible for a distinct set of lab tests. The rapid pace and precise performance creates a high stress level. Most technologists have a four-year degree, while technicians have a two-year degree. Some members of the team are trained on the job, such as phlebotomists (technicians who draw blood).

Administration

Administration is the top level of health care management, including the president, chief executive officer, chief financial officer, chief technology officer, and the vice presidents who assist them. The administrators creates strategic plans and goals so that the health care facility will be an asset to the community while maintaining a financial environment that allows it to continue to provide services and jobs for many years into the future.

Spiritual Care

Health care facilities associated with religious organizations as well as some community-oriented facilities often have a chaplain, priest, or other clergy ministering to the sick within the health care facility. Spiritual care is often associated with improved clinical outcomes, and the author's observations from 28 years of experience in health care

support this. Often, an office and chapel are provided within the health care facility to augment spiritual care.

Information Services/Information Technology Department

From its inception in the late 1960s until the early 1980s, the information services department was referred to as “computer services” or “data processing.” The exponential growth in this sector has radically changed how health care processes and medical devices operate. Adaptations from advances in computer and network technology continue to permeate health care. Hospitals now have their own web pages and intranets, and departments are connected by both intranet and Internet e-mail and common servers. In reality, most medical devices are computers with external sensors that monitor functions or provide curative or palliative care. As a result of the combination of computers and networks in the same workspace, clinical engineering and information services departments find themselves sharing responsibilities. The division of responsibilities is normally the patient-device interface, which is the domain of the clinical engineer. Some health care facilities find it efficient to combine all technology-related services into one branch, the technology department, members of which report to the chief technology officer. Information technology experts maintain and expand the information network, servers, picture archiving, and communications services, while clinical engineers and biomedical equipment technicians maintain, acquire, and consult on medical equipment.

Telecommunications Department

When data processing centers were only closets within health care facilities, the telecommunications department was only a small but important segment of the hospital support group. Each health care facility maintained its own telecommunications system, sometimes rivaling small telephone companies. The result of these large systems was a feature known as the “private branch exchange” (PBX). The PBX was the hub of all incoming and outgoing calls within the hospital. In the late 1990s, innovations such as voiceover internet

protocol (VOIP) and packet information exchange made it possible to combine both voice and data on the same transmission line. This concept is being incorporated into health care infrastructure, with tremendous savings. Most hospitals operate under the top-down management scheme and could be skeptical of new contraptions that benefit the public in general (Cram, 2001). The typical scenario is still a separate telecommunications and information services department, since those who are empowered to implement the new technology hesitate to change or implement technology that is not well understood.

Glossary

- Housekeeper (environmental service): An employee who mops, dusts, waxes floors, and also changes sheets and towels for patients.
- Dietary aid: An employee who delivers carts of food to the nursing units, picks up discarded eating utensils, changes dressings, and bathes patients.
- Nursing assistant (NA). An employee who works with nurses but is not required to have a formal education beyond a high school diploma or GED. This person is taught to take a patient's blood pressure and temperature and to write these values in the patient's chart. This person may also change dressings or bathe patients.
- Respiratory therapy assistant: This person must be able to lift large shifting loads, assist patients with exercise, change dressings, operate whirlpools, massage muscles, and bathe patients.
- Groundskeeper: An employee who mows lawns, trims hedges, sweeps main areas, waters plants, replaces in-ground irrigation systems, and uses compressor to remove water from flooded areas.

112

Construction and Renovation

Matthew F. Baretich

President, Baretich Engineering, Inc.
Fort Collins, CO

Health care delivery organizations construct new facilities and renovate existing ones for a variety of reasons. Population growth and population aging call for more capacity. Consumers demand health care facilities with more amenities in convenient locations. New technologies require new infrastructure and facility support (Hall, 1998). As a result, clinical engineers are likely to be associated with organizations undergoing extensive construction and renovation underway. Because many construction and renovation projects have a medical—technology component, they provide opportunities for clinical engineers to participate in the selection, acquisition, acceptance, and installation of medical equipment. Time and effort invested in this process will pay dividends over many years as the new or renovated facility is used to provide high-quality patient care. The impact of construction and renovation on patient care is addressed in other articles in this clinical engineering handbook.

Additional opportunities are available for clinical engineers who are prepared to assume a larger role on the facility design team. Effective translation of clinical concerns into technical requirements is a critical success factor for health care facility design. Clinical engineers apply this skill on a daily basis in medical—technology management. Knowledge of clinical practice and the clinical environment enables clinical engineers to educate the design team during the entire design process and to see that the resulting facility meets the needs of the clinicians providing patient care. However, making the most of this opportunity requires an understanding of the design and construction process.

Project Stages

A construction or renovation project typically proceeds through the following stages:

- Conceptual planning: Preliminary definition of the project concept, schedule, and budget, based on a business plan that defines the purpose of the project.
- Programming: Development of the project program that specifies the objectives and design criteria for the project.
- Design:
 - Schematic Design (SD): Definition of basic design parameters and features
 - Design Development (DD): Detailed elaboration of the schematic design
 - Construction Documents (CD): Preparation of documents to be used in construction
- Construction: Actual construction of the building
- Occupancy: Acceptance and occupancy of the building

Leaders of successful projects put significant effort into the initial stages of this process to establish a clear consensus among all parties regarding the purpose and objectives of the project. Although it is possible to change course during the later stages, such changes are increasingly expensive and constrained as the project proceeds.

Clinical engineers should be part of the project from the beginning to be of the greatest assistance. Familiarization with basic concepts and current practices will maximize the contributions of a clinical engineer (JCAHO 1997, Miller and Swensson 1995, Miller and Swensson 2002). Additional information regarding the design and construction process is available on the American Institute of Architects web site (www.e-architect.com).

Design and Construction Standards

There are numerous codes and standards that affect the design and construction of health care facilities. Many of these are highly detailed and are used by architects and engineers who specialize in facility design and construction. Discussion of these codes and standards is beyond the scope of this handbook and generally is not relevant to clinical engineers who are involved in projects for their own health care organizations.

However, there are some references with which clinical engineers should be familiar. These references include standards and guidelines from the Joint Commission on Accreditation of Healthcare Organizations (JCAHO), the American Institute of Architects (AIA), and the Association for Professionals in Infection Control and Epidemiology (APIC). A working knowledge of the material in these guidelines will help a clinical engineer become an effective member of the health care facility design team.

JCAHO Standards

In the United States, most health care delivery organizations are guided by the Environment of Care standards of the Joint Commission on Accreditation of Healthcare Organizations. For example, the primary JCAHO standard regarding facility design and construction in hospitals, EC.3.2.1 (JCAHO 2002), states:

When planning for the size, configuration, and equipping of the space of renovated, altered, or new construction, the hospital uses one of the following:

- a) Guidelines for Design and Construction of Hospitals and Health Care Facilities, 1996 ed, published by the American Institute of Architects
- b) Applicable state rules and regulations
- c) Similar standards or guidelines

In practice, most hospitals use the current edition of the American Institute of Architects guidelines (AIA, 2001) as a baseline for facility design. However, adjustments to meet the requirements of local authorities having jurisdiction (AHJs) may be necessary and appropriate in carefully considered cases (with appropriate documentation) to depart from the AIA guidelines to achieve particular organizational objectives.

JCAHO Standard EC.3.2.1 also requires hospitals to conduct a proactive risk assessment as part of demolition, construction, and renovation projects. A discussion of the risk assessment process follows.

JCAHO Environment of Care standards also include broad guidelines describing how the "built environment" should contribute to high-quality patient care. Standard EC.3.1 calls for an environment that "meets the needs of patients, encourages a positive self-image, and respects their human dignity." Standard EC.3.2 requires hospitals to provide "an environment with appropriate space and equipment." Standard EC.3.3 mandates "appropriate privacy to patients." Standard EC.3.4 addresses the role of the environment in supporting "the development and maintenance of the patient's interests, skills, and opportunities for personal growth."

Additional issues for health care facility design can be found throughout the Environment of Care standards. For example, Standard EC.1.6 requires the equipment management plan to include provisions for "selecting and acquiring equipment." Standard EC.1.4 requires the emergency management plan to identify "facilities for radioactive or chemical isolation and decontamination." Standard EC.1.7.1 specifies where emergency electrical power must be provided in the hospital.

The requirements of Standard EC.1.5 to implement "interim life safety measures" (ILSMs) are of particular relevance to the construction phase of a project in order to compensate for the temporary life safety deficiencies that often occur during construction and renovation activities. Construction and renovation projects may also require preparation (for new facilities) or updating (for renovated facilities) of the Statement of Conditions compliance documents required by Standard EC.1.5.1.

Many of these specific design and construction related issues are covered in more detail elsewhere in this handbook. The main point is that the design of a fully JCAHO-compliant health care facility requires familiarity with the entire set of JCAHO Environment of Care standards.

AIA Guidelines

The American Institute of Architects (AIA) publication, *Guidelines for Design and Construction of Hospital and Health Care Facilities* (AIA 2001), is a valuable reference that provides concise information in a format that is accessible to clinical engineers and other health care professionals who are not facility design specialists. It is also a primary resource for health care facilities, and is cited in JCAHO Environment of Care standards.

The document provides specific guidelines for a vast array of design issues, including the minimum size for a patient room, the number of oxygen outlets at an ICU bed location, and the number of air changes per hour for an operating room. It also highlights key aspects of the design and construction process and provides guidelines for handling critical issues.

Infection control is one critical issue addressed in the 2001 edition of the AIA guidelines. The guidelines now mandate an Infection Control Risk Assessment (ICRA) process for each construction and renovation project. The ICRA process is defined as "a determination of the potential risk of transmission of various [infectious] agents in the facility." During the design phase of the project, infection control requirements identified in the ICRA process become design parameters (e.g., the number of airborne infection isolation [AII] or "negative pressure" rooms required). During the construction phase, construction policies and procedures are implemented to mitigate the infection control risks identified in the ICRA process (e.g., the installation of airtight barriers between the construction area and adjacent patient care areas).

The Association for Professionals in Infection Control and Epidemiology (APIC) offers extensive information on infection control issues associated with construction and renovation, including practical procedures for implementing the ICRA process (Bartley 1999). The ICRA portion of the APIC material may be downloaded from the American Society for Health care Engineering web site (www.ashe.org).

Risk Assessment

As mentioned above, JCAHO Environment of Care standards call for a proactive risk assessment to "identify hazards that could potentially compromise patient care in occupied areas of the hospital's buildings" due to demolition, construction, or renovation. The items to consider include air quality requirements, infection control, utility requirements, noise, vibration, and emergency procedures. The ICRA process described in the AIA guidelines is only one component of the wide-ranging JCAHO risk assessment process.

In the health care delivery system, many risk assessment processes involve the translation of clinical concerns into technical requirements (e.g., a description of clinical procedures to be performed is translated into specifications for mechanical and electrical systems). The inputs to the process come from clinical professionals and the outputs go to technical professionals. Clinical engineers have the opportunity to bridge the communication gap between these two professional groups and to ensure that the output accurately represents the input.

Clinical Engineering in Construction and Renovation

At first glance, the role of clinical engineering in construction and renovation might appear to be limited to medical equipment selection. This is a critical role for clinical engineers and it is thoroughly addressed other articles in this handbook. (See Chapters 30-34.) However, the purpose of this article is to expand the perceived role of clinical engineering in two dimensions. First, clinical engineers should be involved at every phase of the project from conceptual planning (e.g., investigation of emerging technologies) through occupancy (e.g., planning for the safe transfer of patients to the new facility). Clinical engineers can make valuable contributions at every stage and should be brought onto the design team at the onset when the project direction is being set.

Second, clinical engineers should be involved in aspects of the project beyond medical technology. Any aspect of the project that involves translating clinical concerns into technical specifications is an opportunity for clinical engineering. The ICRA process previously outlined is one example; many other activities (e.g., design of mechanical and electrical systems, specification of department orientation and patient room configurations, definition of space and equipment requirements for support areas) can benefit from a clinical engineer's involvement.

Summary

Clinical engineers have many opportunities to become valued members of the design team for construction and renovation projects. To make the most of these opportunities, clinical engineers must expand their knowledge of the design and construction process and should see their roles as encompassing more than medical equipment. They also need to insist on active involvement at every stage of the design and construction process. Through broad-scale participation in construction and renovation activities, the clinical engineering field expands its contributions to safe and effective patient care.

Radiation Safety

Jadwiga (Jodi) Strzelczyk

Assistant Professor of Radiology, Radiological Sciences
Division, University of Colorado, Health Sciences Center,
Denver, CO

Brief Historical Review of Major Radiation Discoveries

The radiation story began at the end of 19th century. In November 1895, a German/Dutch physicist, Wilhelm Conrad Roentgen discovered mysterious penetrating rays while investigating the passage of an electrical discharge from an induction coil through a partially evacuated glass tube. He called them "X rays." Just a few months later, in March 1896, a French professor of physics, Antoine Henri Becquerel, discovered a peculiar property of certain fluorescent materials; they were capable of creating their own images on photographic plates wrapped in light-tight black paper. The newly discovered phenomenon was coined "radioactivity" by Mme Maria Skłodowska-Curie. This Polish scientist, while working with her husband, the French professor Pierre Curie, on purification of uranium pitchblende ore, separated the radioactive element radium in December 1898 (Strzelczyk, 1999). These discoveries found immediate applications, perhaps the most significant ones being in medicine.

Any progress comes at a price. As it frequently happens with new technologies, harmful effects of prolonged radiation exposures were not immediately known. While certain adverse effects became obvious just months after Roentgen's discovery, others came later due to a latency period. The latter was, no doubt, one of the major contributors to the delay in the acceptance of radiation protection procedures. Lack of radiation measurement units was another; for a number of years, erythema on patient's skin was considered an indicator of an appropriate dose. General radiation protection measures were eventually adopted following the establishment of the International Radiation Protection Committee (ICRP) in 1928. Its initial recommendations were directed at medical practice, but current ones are applicable to a wide range of uses of radiation. Shortly after the formation of the ICRP, the National Council on Radiation Protection and Measurements (NCRP) was established in the United States with a mission similar to that of the ICRP.

Then came World War II. Marking the fiftieth anniversary of Roentgen's discovery, the year 1945 saw the devastating detonations of three new weapons. The first test atomic bomb exploded over the Alamogordo military grounds, in the White Sands desert of New Mexico (Trinity site). It was fueled with the fissionable element plutonium, which was discovered by a team of scientists lead by Glen Seaborg, an American scientist of Swedish ancestry, in 1941. The next two bombs, containing uranium and plutonium, respectively, leveled two Japanese cities, Hiroshima and Nagasaki. In spite of the enormous human toll of these detonations, more than on 100 test explosions above ground were held by the United States, the Soviet Union, Great Britain, China, and France following WWII. These events took place until the "Non-Proliferation Treaty" (NPT) was negotiated by the members of the United Nations (UN). The NPT came into effect in 1970 (Henderickx, 1998).

There is a common misconception that research during WWII was limited to the development of the atomic bomb. While it is true that this aspect was emphasized, research of the WWII and post-war era encompassed work on new peaceful applications of discoveries such as clean generation of electric power, the development of radiation measuring techniques and instrumentation, and in-depth studies of radiation effects. The world continues to benefit from these discoveries.

In the field of medicine, radiation and radioisotopes far exceeded the potential that early researchers had hoped for. Currently, more than half of the patients admitted to U.S. hospitals are diagnosed or treated using radioisotopes. Many of these isotopes are the "by-products" that occur during the operation of nuclear reactors.

The use of radiation and radioactive materials requires special precautions, but many benefits are possible when such uses are carried out in a responsible fashion. With a growing number of applications of radiation and radioisotopes in medicine for diagnostic and therapeutic purposes, the role, scope, organization, and structure of radiation protection programs in medical facilities continues to evolve.

Radiation Safety Program Philosophy

Recent ICRP Publication 73 (ICRP, 1996) reviewed the recommended framework for radiological protection. It reinforced the view that the primary aim of radiological

protection is to provide an appropriate standard of protection for man without unduly limiting the beneficial practices giving rise to radiation exposure.

The ICRP system of protection is based on the following three objectives:

1. To prohibit radiation exposure to individuals unless a benefit to the exposed individuals and to the society can be demonstrated, and be sufficient to balance any detriment
2. To provide adequate protection to maximize the net benefit, taking into consideration economic and social factors
3. To limit the dose (other than from medical exposures) received by individuals as a result of all uses of radiation

In the United States and in many countries throughout the world, regulations promulgated by regulatory authorities require medical facilities to maintain radiation safety programs. While these programs differ from one another, depending on the type of industry and scope of activities, each is based on a generic template and should contain the key components described in the ICRP system. In addition, such programs must satisfy numerous prescriptive requirements.

Licensing and Registration

Establishing and maintaining a well-organized medical radiation safety program requires operational and technical knowledge of an experienced medical health physicist. A model program for medical uses of radioactive materials can be found in the U.S. Nuclear Regulatory Commission (NRC) Guide 10.8 (USNRC, 1987).

Any individual or institution in the U.S. who intends to engage in such uses must obtain the services of a qualified physicist who will, on their behalf, prepare and file an application with an appropriate regulatory agency, the NRC or an Agreement State agency. At the time of writing, the majority of states have entered into an agreement with the NRC to develop their own state radiation control programs that oversee radioactive materials licensees with their respective states. Although preparation of radioactive materials license (RAM) applications is straightforward, it is quite a laborious process. In the completion of such applications for medical uses, one should refer to the NRC Guide 10.8 as well as appropriate parts of the U.S. NRC (Code of Federal Regulations) and/or state regulations pertinent to radiation control.

Support of an institution's management in this process cannot be overemphasized. Of note is the fact that any statement made in the application potentially will become part of the license conditions that are subject to regulatory compliance inspections. Thus, while the goal is to have a sound radiation safety program, one should not commit to policies and procedures for which the resources are not available or to which the institution's management has not explicitly agreed (Trueblood and Furr, 1993).

Slightly different requirements apply to ionizing radiation-producing equipment. The Food and Drug Administration (FDA) within the U.S. Department of Health and Human Services (HHS) requires that such equipment, intended for human use, must meet the criteria of the Federal Performance Standard (FDA). The owner or operator of radiation-producing equipment is obligated to register it with an appropriate state agency and to operate it in accordance with the regulatory provisions.
